The Strategic Impact of Higher-Order Beliefs*

January 26, 2013

Abstract

Previous research has established that the predictions of game theory are quite sensitive to the assumptions made about the players’ beliefs. We evaluate the severity of this robustness problem by characterizing conditions on the primitives of the model—the players’ beliefs and higher-order beliefs about the payoff-relevant parameters—for the behavior of a given Harsanyi type to be approximated by the behavior of (a sequence of) perturbed types. This amounts to providing belief-based characterizations of the strategic topologies of Dekel, Fudenberg, and Morris (2006). We apply our characterizations to a variety of questions concerning robustness to perturbations of higher-order beliefs, including genericity of types that are consistent with a common prior, and we investigate the connections between our notions of robustness and the notion of common p-belief of Monderer and Samet (1989).

Keywords: Games with incomplete information, rationalizability, higher-order beliefs, robustness

JEL Classification: C70, C72.

*We are especially grateful to Eddie Dekel, Jeffrey Ely, Stephen Morris and Marcin Pęski for numerous stimulating discussions and insightful comments. We also thank Pierpaolo Battigalli, Drew Fudenberg, Atsushi Kajii, Barton Lipman, George Mailath, Hervé Moulin, Daisuke Oyama, Muhame Yildiz, and participants at various seminars and conferences for helpful comments. Eduardo Faingold and Siyang Xiong thank the National Science Foundation (grants SES-1227593 and SES-1227620) for financial support.

1 Introduction

A major concern with non-cooperative game theory is its reliance on details. The formal description of a strategic situation as a game requires informational assumptions that are often not verifiable in full detail by the analyst in real life, such as the players’ beliefs about the precise order of moves, the actions available to the players when they move, and their exact payoff functions. Unfortunately, game theoretic solutions are known to depend sensitively on those assumptions. For example, in an exchange economy with uncertainty, where agents share a common prior on the underlying state of the world, there is no feasible trade that is commonly known to be mutually acceptable (Milgrom and Stokey, 1982), whereas such a trade can exist if the common prior and common knowledge assumptions are slightly violated (Morris, 1994). In auction environments, bidders with independent values retain information rents (Myerson, 1981), while the auctioneer can fully extract their surplus when their values are slightly correlated (Crémer and McLean, 1988).¹ In the alternating-offers bargaining model of Rubinstein (1982), players reach an immediate agreement in the unique (subgame perfect) equilibrium, but delay to agreement is possible in equilibrium when the players have heterogeneous beliefs about who will make an offer in each period (Yildiz, 2003). In all these disparate and prominent economic scenarios, a model that makes unwarranted informational assumptions may deliver predictions that are not robust.

What form of misspecification error can be allowed in a model of the players’ beliefs, to ensure the model will deliver robust predictions across a wide range of economic situations? Focusing on strategic-form games with incomplete information, we take the point of view of the analyst who posits a type space (Harsanyi, 1967-68) to model the players’ uncertainty, and recognizes that his model may be misspecified. For example, he may assume that there is common knowledge of the true payoff-relevant parameter, but understands that such common knowledge assumption can be at best an approximation of reality. Or, as is often the case in practice, he may posit a finite type space, or a type space with a common prior, but realizes that the true type space may be larger, or that the true common prior distribution may be slightly different from the one assumed, or even that the players may have slightly different priors. To analyze the impact of such kinds of misspecifications, we study the tail properties of the hierarchies of beliefs encoded in the Harsanyi types—a player’s beliefs about the payoff-relevant parameters, his beliefs about the other players’ beliefs about the payoff-relevant parameters, and so on, ad infinitum—and their implications for behavior. Our main finding is an exact characterization of what it takes for a pair of types to display similar strategic behaviors. Thus, we measure the minimum level of precision of the analyst’s information model that is required for accurate predictions of strategic play.

To explain our results we first need to be precise about what we mean by “strategic behavior.” Our behavioral assumption is that players play a Bayesian equilibrium on a type space (possibly

¹Full surplus extraction has also been itself the subject of a debate concerning whether, and in what sense, it is a robust result. See Heifetz and Neeman (2006) and Chen and Xiong (2012).
without a common prior). Thus, from the perspective of the analyst, who does not know the true type space of the players and has a concern for robustness, the relevant solution concept is (interim correlated) rationalizability (Dekel, Fudenberg, and Morris, 2006). Indeed, the set of actions that are rationalizable for a type $t$ coincides with the set of actions that can be played in some Bayesian equilibrium on some type space, by some type that has the same hierarchy of beliefs as $t$ (Dekel, Fudenberg, and Morris, 2007, Remark 2). A similar perspective is taken by Bergemann and Morris (2009) in the context of robust mechanism design. See also Aumann (1987) and Brandenburger and Dekel (1987) for early papers pioneering this approach.

Formally, our main results are characterizations of the strategic topology and the uniform strategic topology of Dekel, Fudenberg, and Morris (2006). The former is the coarsest topology on the universal type space (Mertens and Zamir, 1985)—the space of all hierarchies of beliefs—under which the correspondence that maps each type of a player into his set of rationalizable actions displays the same kind of continuity properties that the best-reply, Nash equilibrium and rationalizability correspondences exhibit in complete information games.\(^2\) Thus, for any player, a sequence of types $t^n$ converges in the strategic topology to a type $t$ if and only if, for every finite game and every action $a$ of the player in the game, the following conditions are equivalent: (a) action $a$ is rationalizable for type $t$; (b) for every $\varepsilon > 0$ and sufficiently large $n$, action $a$ is $\varepsilon$-rationalizable for type $t^n$, where $\varepsilon$ is a size of sub-optimization allowed in the incentive constraints. Convergence in the uniform strategic topology adds the requirement that the rate of convergence in (b) be uniform across all finite games (with uniformly bounded payoffs).

As shown by Dekel, Fudenberg, and Morris (2006), a sequence of types converges in the strategic topology only if it converges in the product topology: for every integer $k \geq 1$, the sequence of $k$-order beliefs must converge weakly. However, the Electronic Mail game of Rubinstein (1989) and, more generally, the structure theorem of Weinstein and Yildiz (2007), show that convergence in the product topology does not imply strategic convergence. Our characterizations are based on a strengthening of product convergence that requires $k$-order beliefs to converge at a rate that is uniform in $k$.

We first explain the characterization of the uniform strategic topology, as it is simpler to state and can serve as a benchmark for the other characterization result. For each $k$, endow the space of $k$-order beliefs with the Prohorov distance, which is a standard distance that metrizes the topology of weak convergence of probability measures (Billingsley, 1999). Say that a sequence of types $t^n$ converges uniformly to a type $t$ if the $k$-order belief of $t^n$ converges to the $k$-order belief of $t$ and the rate of convergence is uniform in $k$. Our first main result, Theorem 1, states that uniform strategic convergence is equivalent to uniform weak convergence.\(^3\) To interpret, consider

\(^2\) See the introduction of Dekel, Fudenberg, and Morris (2006) for a precise analogy with complete information games.

\(^3\) The partial result that uniform weak convergence implies uniform strategic convergence was proved in Chen, Di Tillio, Faingold, and Xiong (2010). The reverse implication is new to the present paper.
an analyst who would like to make predictions with some minimal level of accuracy, and wants to achieve this level of accuracy uniformly across all strategic situations that the players might face.\footnote{This may be the case if the analyst is a mechanism designer who will ultimately determine the game that the players will face by his choice of a mechanism.} A tight condition for such uniformly robust prediction is that the analyst’s model of the players’ beliefs and higher-order beliefs be sufficiently precise, with the required degree of precision, as measured by the Prohorov distance, binding uniformly over all levels of the belief hierarchy.

The content of Theorem 1 can be dissected in two parts. First, the theorem underscores the role of uniform convergence of hierarchies of beliefs as a requirement for robustness. In light of the structure theorem of Weinstein and Yildiz (2007), which shows that the tails of the hierarchies of beliefs can have a large impact on strategic behavior, the role of uniform convergence should not come as a surprise. Second, the theorem quantifies the impact of a misspecification at each order of the hierarchy by the Prohorov distance. We view this as a nontrivial part of the theorem. Indeed, the Prohorov distance, on which the notion of uniform weak convergence is based, is but one of many equivalent distances that metrize the topology of weak convergence of probability measures. For any such distance, one can consider the associated uniform distance over infinite hierarchies of beliefs. It turns out that these distances may generate different topologies over infinite hierarchies, even though the induced topologies over $k$-order beliefs coincide for each finite $k$.\footnote{In Chen, Di Tillio, Faingold, and Xiong (2010) we report an example of a sequence of types that converges uniform weakly but fails to converge in the uniform topology associated with a distance (different from Prohorov) that metrizes the topology of weak convergence of probability measures.} Theorem 1 identifies one of these uniform distances that ultimately characterizes the uniform-strategic topology.

The characterization of the strategic topology (Theorem 2) is also based on uniform convergence and the Prohorov metric, but is more subtle. The relevant class of events for uniform weak convergence, and a fortiori, uniform strategic convergence, is the entire Borel $\sigma$-algebra of the universal type space. By contrast, our characterization of the strategic topology highlights the role of coarser information structures called frames. A frame is a profile of finite partitions of the universal type space—one partition for each player—that satisfies a measurability condition: each player’s belief concerning the events in the frame must pin down a unique atom of that player’s partition. (We discuss the meaning of this condition below.) For any frame $\mathcal{P}$ and any positive integer $k$, we define a distance over types, $d_k^{\mathcal{P}}$, that is analogous to the Prohorov distance over $k$-order beliefs, but restricts the events for which the proximity is measured to those in the frame $\mathcal{P}$. Say that a sequence of types $t^n$ converges to a type $t$ uniform-weakly on $\mathcal{P}$ if, for every positive integer $k$, $t^n$ converges to $t$ under $d_k^{\mathcal{P}}$ and the rate of convergence is uniform in $k$. Our second main result, Theorem 2, states that a sequence of types converges strategically if and only if it converges uniform-weakly on every frame.

A frame can be interpreted as a coarsening of the canonical information structure of the universal type space where each player is assumed to know only his belief about the payoff-relevant
states and the events in the other players’ partitions (the events the player “can reason about”).
The measurability condition is a natural epistemic condition for a model of coarse information
in a multi-agent setting: it amounts to the requirement that every event concerning player \( j \) that
player \( i \) can reason about is either known to be true or known to be false by player \( j \). Since the
strategic behavior of a player in a game can only be affected by events that the player knows, it is
intuitive that strategic convergence should imply uniform-weak convergence only on frames and
not on all information structures.

To shed further light on the impact of higher-order beliefs, we use our characterization to
investigate the connection between strategic convergence and a natural notion of uniform conver-
gence based on common \( p \)-beliefs (Monderer and Samet, 1989).\(^6\) Say that a sequence of types \( t^n \)
converges in common beliefs to a type \( t \) if \( t^n \) converges to \( t \) in the product topology and, for every
event \( E \) and every \( p \geq 0 \), the following conditions are equivalent: (i) \( E \) is common \( p \)-belief for

\[ \text{type } t; \text{ (ii) for every } \varepsilon > 0, k \geq 1 \text{ and sufficiently large } n, \text{ type } t^n \text{ has common } (p - \varepsilon)\)-belief on \]
the event that the players have \( k \)-order beliefs that are \( \varepsilon \)-close to those from \( E \). This is the interim
analogue of the ex ante notion of convergence based on common \( p \)-beliefs, which the seminal
papers of Monderer and Samet (1996) and Kajii and Morris (1998) have shown to characterize the
ex ante strategic topology for Bayesian equilibrium on countable common prior type spaces.

We establish, using the characterization of Theorem 2, that strategic convergence implies con-
vergence in common beliefs (Theorem 3). But, somewhat surprisingly, we find that the converse
fails: we exhibit a sequence of types that converges in common beliefs but does not converge
uniform-weakly on a frame (Example 5). These results highlight a fundamental difference be-
tween the common prior, equilibrium, ex ante framework of the early literature and our non-
common prior, non-equilibrium, interim framework. Nonetheless, when the limit is assumed a
finite type—a type that belongs to a finite type space—we show that convergence in common be-
liefs is equivalent to uniform weak convergence, and hence, a fortiori, to both uniform strategic
and strategic convergence (Theorem 4).

Finally, we use our characterizations to revisit, and reverse, two important genericity results
concerning the structure of the universal type space. The first result, due to Ely and Peški (2011),
shows that critical types—those types which display discontinuous rationalizable behavior—form
a meager set under the product topology. By way of contrast, we show that they form an open
and dense set under the strategic topology (Theorem 5). Second, Lipman (2003) shows that types
consistent with a common prior are dense in the universal type space under the product topology.
Instead, we show that those types are nowhere dense under the strategic topology (Theorem 6).
We also report measure-theoretic versions of these genericity results based on the notions of preva-
ience and shyness.

The rest of the paper is organized as follows. Section 2 sets up the incomplete information

\(^6\) An event \( E \) is common \( p \)-belief for a given type if that type assigns probability at least \( p \) to \( E \), assigns probability
at least \( p \) to the event that \( E \) obtains and the other players assign probability at least \( p \) to \( E \), and so forth, ad infinitum.
model and reviews the basic definitions and properties of type spaces, hierarchies of beliefs, common \( p \)-beliefs and the solution concept of interim correlated rationalizability. Section 3 presents the strategic topologies of Dekel, Fudenberg, and Morris (2006) and their characterizations in terms of beliefs, and studies their relationship with the notion of common \( p \)-belief of Monderer and Samet (1989). Section 4 examines the genericity of critical types and common prior types under the strategic topology and also their measure-theoretic genericity. All proofs are presented in the appendix.

2 Preliminaries

Given a measurable space \( S \), write \( \Delta(S) \) for the space of probability measures on \( S \), equipped with the \( \sigma \)-algebra generated by the sets of the form \( \{ v \in \Delta(S) : v(E) \geq p \} \), where \( E \subseteq S \) is a measurable set and \( p \in [0, 1] \). Unless otherwise stated, product spaces are assumed to be endowed with the product \( \sigma \)-algebra, subspaces with the relative \( \sigma \)-algebra, and finite spaces with the discrete \( \sigma \)-algebra.

We consider two-player games with incomplete information.\(^7\) The space \( \Theta \) of payoff-relevant states (or just states, for short) is assumed to be finite, with \( \# \Theta \geq 2 \), and is fixed throughout the paper. A game is a profile \( G = (A_i, g_i)_{i \in I} \), where \( A_i \) is a finite set of actions of player \( i \in I = \{1, 2\} \) and \( g_i : A_i \times A_{-i} \times \Theta \rightarrow \mathbb{R} \) is his payoff function, which is extended to \( \Delta(A_i) \times \Delta(A_{-i} \times \Theta) \) in the usual way.\(^8\) The uncertainty of the players is modeled by a type space, that is, a profile \( (T_i, \phi_i)_{i \in I} \) where \( T_i \) is a measurable space of types of player \( i \) and \( \phi_i : T_i \rightarrow \Delta(\Theta \times T_{-i}) \) is a measurable map that associates, with each type \( t_i \) of player \( i \), his belief \( \phi_i(t_i) \) about the payoff-relevant states and the types of player \(-i\).

2.1 Solution Concept

Our analysis is based on the solution concept of interim correlated rationalizability, due to Dekel, Fudenberg, and Morris (2007). The concept is an incomplete information extension of the rationalizability of Bernheim (1984) and Pearce (1984).

Given a game \( G = (A_i, g_i)_{i \in I} \) and \( \varepsilon \geq 0 \), an action \( a_i \in A_i \) is an \( \varepsilon \)-best reply to \( \pi_{-i} \in \Delta(A_{-i} \times \Theta) \), written \( a_i \in BR_i(\pi_{-i}, G, \varepsilon) \), if \( g_i(a_i, \pi_{-i}) \geq g_i(a'_i, \pi_{-i}) - \varepsilon \) for all \( a'_i \in A_i \). Given a type space \( (T_i, \phi_i)_{i \in I} \), a profile of correspondences \( \xi_i : T_i \Rightarrow A_i, i \in I \), has the \( \varepsilon \)-best-reply property if for each \( i \in I \), \( t_i \in T_i \) and \( a_i \in \xi_i(t_i) \) there is a conjecture \( v \in \Delta(\Theta \times T_{-i} \times A_{-i}) \)

---

\(^7\)We restrict attention to two-player games for ease of notation. All our results extend to the general \( N \)-player case.

\(^8\)Following standard notation, for each player \( i \in I \) we write \(-i\) to designate the other player in \( I \).
such that the following conditions hold:
\[
\text{marg}_{\Theta \times T_{-i}} v = \phi_i(t_i),
\]
\[
\left( \text{marg}_{T_{-i} \times A_{-i}} v \right) \left[ \text{graph } \xi_{-i} \right] = 1,^9
\]
\[
a_i \in BR_i \left( \text{marg}_{A_{-i} \times \Theta} v, G, \varepsilon \right).
\]

The greatest (w.r.t. pointwise set inclusion) profile of correspondences that has the \( \varepsilon \)-best-reply property is the interim correlated \( \varepsilon \)-rationalizable correspondence—or \( \varepsilon \)-rationalizable correspondence, for short—and is denoted \( R_i(\cdot, G, \varepsilon) : T_i \Rightarrow A_i \). For \( a_i \in R_i(t_i, G, \varepsilon) \), we say that \( a_i \) is an \( \varepsilon \)-rationalizable action for type \( t_i \). Finally, to ease notation, for \( \varepsilon = 0 \) we denote the correspondence \( R_i(\cdot, G, 0) \) simply by \( R_i(\cdot, G) \) and call it the (interim correlated) rationalizable correspondence.

2.2 Beliefs

Type spaces contain implicit descriptions of each player’s beliefs about the payoff-relevant states, his beliefs about the other player’s beliefs about the payoff-relevant states, and so on. We formulate this higher-order uncertainty following Mertens and Zamir (1985), whose construction we now review. An equivalent formulation is found in Brandenburger and Dekel (1993).

A first-order belief of player \( i \) is a probability distribution over \( \Theta \), that is, an element of \( T_i^1 = \Delta(\Theta) \). Recursively, for \( k \geq 2 \), the space of \( k \)-order beliefs of player \( i \) is
\[
T_i^k = \left\{ (t_i^1, \ldots, t_i^{k-1}, t_i^k) \in T_i^{k-1} \times \Delta(\Theta \times T_{-i}^{k-1}) : \text{marg}_{\Theta \times T_{-i}} t_i^k = t_i^{k-1} \right\}.
\]
The above condition on marginal distributions implies that each element of \( T_i^k \) is uniquely determined by its \( k \)-th coordinate, hence we can identify \( T_i^k \) with \( \Delta(\Theta \times T_{-i}^{k-1}) \). The space of hierarchies of beliefs of player \( i \) is
\[
T_i = \left\{ (t_i^1, t_i^2, \ldots) : (t_i^1, \ldots, t_i^k) \in T_i^k \quad \forall k \geq 1 \right\}.
\]

Mertens and Zamir (1985) show that for every hierarchy \( t_i = (t_i^1, t_i^2, \ldots) \in T_i \) there is a unique probability measure \( \mu_i(t_i) \in \Delta(\Theta \times T_{-i}) \) that extends each of the measures \( t_i^1, t_i^2, \ldots \). Moreover, the map \( \mu_i : T_i \rightarrow \Delta(\Theta \times T_{-i}) \) is an isomorphism.\(^11\) To ease notation, for each event \( E \subseteq \Theta \times T_{-i} \) we shall often write \( \mu_i(E \mid t_i) \) instead of the more cumbersome \( \mu_i(t_i)[E] \).

---

^9When graph \( \xi_i \) is not measurable, this expression is taken to mean that \( \text{marg}_{T_{-i} \times A_{-i} \mid \xi_i} v \) assigns probability one to a measurable subset of graph \( \xi_i \).

^10Such greatest profile of correspondences is well defined, because the pointwise union of any family of profiles of correspondences with the \( \varepsilon \)-best-reply property must also have the \( \varepsilon \)-best-reply property. The \( \varepsilon \)-rationalizable correspondence has an alternative characterization in terms of iterated elimination of actions that are never an interim best-reply (Dekel, Fudenberg, and Morris, 2007, Claim 1) and a dual characterization in terms of iterated elimination of strongly interim-dominated actions (Chen, Di Tillio, Faingold, and Xiong, 2010, Proposition 1).

^11That is, a measurable bijection with measurable inverse.
The type space $(\mathcal{T}_{i}, \mu_{i})_{i \in I}$ is called the universal type space, since any type $t_{i}$ from any abstract type space $(\mathcal{T}_{i}, \phi_{i})_{i \in I}$ uniquely induces a hierarchy of beliefs $\tau_{i}(t_{i}) = (\tau_{i}^{1}(t_{i}), \tau_{i}^{2}(t_{i}), \ldots)$ in a natural way: $\tau_{i}^{1}(t_{i}) = \arg_{\Theta} \phi_{i}(t_{i})$ and, recursively, for $k \geq 2$,

$$\tau_{i}^{k}(t_{i})[\theta \times E] = \phi_{i}(t_{i})\left[\theta \times (\tau_{i}^{k-1}(t_{i}))^{-1}(E)\right]$$

for each $\theta \in \Theta$ and measurable $E \subseteq \mathcal{T}_{i}^{k-1}$, as shown by Mertens and Zamir (1985).

We restrict attention throughout to types that belong to the universal type space $\mathcal{T}_{i}$. This incurs no loss of generality, as Dekel, Fudenberg, and Morris (2007) have shown that the $\varepsilon$-rationalizable actions of any type are pinned down by its hierarchy of beliefs: $R_{i}(t_{i}, G, \varepsilon) = R_{i}(\tau_{i}(t_{i}), G, \varepsilon)$ for any type $t_{i}$ belonging to any type space. Thus, we take $\mathcal{T}_{i}$ to be the domain of the correspondence $R_{i}(\cdot, G, \varepsilon)$.

### 2.3 Common Beliefs

A standard approach to express assumptions about higher-order uncertainty uses the notion of common belief, due to Monderer and Samet (1989, 1996). Let $\Omega = \Theta \times \mathcal{T}_{i} \times \mathcal{T}_{j}$ and, for each measurable set $E \subseteq \Omega$ and each type $t_{i} \in \mathcal{T}_{i}$, let $E_{t_{i}}$ designate the section of $E$ over $t_{i}$, i.e.

$$E_{t_{i}} = \{ (\theta, t_{-i}) : (\theta, t_{1}, t_{2}) \in E \}.$$  

which is a measurable set by standard arguments. For each $p \in [0, 1]$, define

$$B_{i}^{p}(E) = \{ t_{i} \in \mathcal{T}_{i} : \mu_{i}(E_{t_{i}} | t_{i}) \geq p \},$$

which is also measurable. Then, for each $p = (p_{1}, p_{2}) \in [0, 1]^{2}$, define the event that $E$ is mutual $p$-belief as

$$B^{p}(E) = \Theta \times B_{i}^{p_{1}}(E) \times B_{j}^{p_{2}}(E),$$

and the event that $E$ is common $p$-belief as

$$C^{p}(E) = B^{p}(E) \cap B^{p}(E \cap B^{p}(E)) \cap \cdots .$$

Then, the event that $E$ is common $p$-belief for player $i$, written $C_{i}^{p}(E)$, is defined as the projection of $C^{p}(E)$ on $\mathcal{T}_{i}$, which is a measurable set because $C^{p}(E)$ is a rectangle. For notational convenience, we identify $B_{i}^{p_{i}}(E)$ and $C_{i}^{p}(E)$ with the cylinders $\Theta \times B_{i}^{p_{i}}(E) \times \mathcal{T}_{-i}$ and $\Theta \times C_{i}^{p}(E) \times \mathcal{T}_{-i}$.

---

12 The measurability of $B_{i}^{p}(E)$ follows from the measurability of the map $t_{i} \mapsto \mu_{i}(E_{t_{i}} | t_{i})$. The class of events

$$\{ E \subseteq \Omega : E \text{ is a measurable set such that } t_{i} \mapsto \mu_{i}(E_{t_{i}} | t_{i}) \text{ is measurable} \}$$

can be readily verified to be a monotone class containing the algebra of finite disjoint unions of measurable rectangles, which generates the product $\sigma$-algebra on $\Omega$. It follows that the map $t_{i} \mapsto \mu_{i}(E_{t_{i}} | t_{i})$ is measurable for every measurable $E$.

13 The definition of $C^{p}(E)$ is analogous to the common repeated belief of Monderer and Samet (1996), which differs from the original definition of Monderer and Samet (1989). A similar definition appears in Ely and Peski (2011) for the case where $E$ is a rectangle. We allow the event $E$ to be any measurable set.
respectively. Thus, we can write

\[ C^p_i(E) = B^p_i(E) \cap B^p_i(E \cap B^{-i}_p(E)) \cap B^p_i(E \cap B^{-i}_p(E \cap B^p_i(E))) \cap \cdots. \]

Note that for \( p_{-i} = 0 \) we have \( C^p_i(E) = B^p_i(E) \).

Finally, common belief has the following well-known fixed-point characterization.

**Lemma 1.** \( C^p(E) = B^p(E \cap C^p(E)) \) and \( C^p_i(E) = B^p_i(E \cap C^p_i(E)) \).

### 3 Behavior- and Belief-Based Topologies

Two kinds of information are encapsulated in the description of a type. On one hand, a type generates an infinite hierarchy of beliefs. On the other hand, a type determines the player’s strategic behavior in each game. Accordingly, we distinguish between belief-based topologies on types—under which, by definition, nearby types have similar hierarchies of beliefs—and behavior-based topologies—under which nearby types display similar strategic behaviors. In this section, we provide belief-based characterizations of behavior-based topologies.

The **product topology** is the canonical belief-based topology on the universal type space \( T_i \). To define it, let the (finite-dimensional) space of first-order beliefs, \( T^1_i = \Delta(\Theta) \), be endowed with the Euclidean topology and, recursively, for each \( k \geq 2 \), let the space of \( k \)-order beliefs, \( T^k_i = \Delta(\Theta \times T^{-i}_{-k}) \), be endowed with the topology of weak convergence of probability measures relative to the topology defined on \( T^{-i}_{-k-1} \). Then, a sequence of types \( t^n_i \) converges to a type \( t_i \) in the product topology if the \( k \)-order belief of \( t^n_i \) converges to the \( k \)-order belief of \( t_i \), for every \( k \geq 1 \).

Turning to behavior topologies, we first review the key definitions of Dekel, Fudenberg, and Morris (2006).

**Definition 1** (Strategic topology). A sequence of types \( t^n_i \) converges strategically to a type \( t_i \) if for every game \( G \) and every action \( a_i \) of player \( i \) in \( G \), the following conditions are equivalent:

(a) \( a_i \) is rationalizable for \( t_i \) in \( G \)
(b) for every \( \epsilon > 0 \) there exists \( N \) such that for every \( n \geq N \), \( a_i \) is \( \epsilon \)-rationalizable for \( t^n_i \) in \( G \).

---

\(^{14}\)Since \( \Theta \) is finite, the Borel \( \sigma \)-algebra of the product topology on \( T_i \) coincides with the \( \sigma \)-algebra obtained in the topology-free formulation of Section 2.2. Likewise, the Borel \( \sigma \)-algebra on \( \Delta(\Theta \times T^{-i}) \) generated by the topology of weak convergence of probability measures (induced by the product topology on \( T^{-i} \)) coincides with the \( \sigma \)-algebra of our topology-free formulation. Finally, if we endow each \( T_i \) with the product topology and \( \Delta(\Theta \times T^{-i}) \) with the topology of weak convergence of probability measures, then \( T_i \) and \( \Delta(\Theta \times T^{-i}) \) are compact metrizable and \( \mu_i : T_i \to \Delta(\Theta \times T^{-i}) \) is a homeomorphism.
The strategic topology is the topology of strategic convergence on $T_i$.\footnote{That is, by definition, a set $F \subseteq T_i$ is closed under the strategic topology if it contains the limit points of all strategically convergent sequences in $F$. Alternatively, the strategic topology can be defined as the topology generated by the collection of sets having either the form $\{t_i \in T_i : a_i \notin R_i(t_i, G, \gamma)\}$ or the form $\{t_i \in T_i : a_i \in \cup_{\gamma' < \gamma} R_i(t_i, G, \gamma')\}$ and can be shown to be metrizable.}

The implication from (b) to (a)—for every game $G$ and action $a_i$ of player $i$ in $G$—is a form of upper hemi-convergence of the rationalizable correspondence, and is equivalent to convergence in the product topology (Dekel, Fudenberg, and Morris, 2006, Theorems 1 and 2). In turn, the implication from (a) to (b) is a form of lower hemi-convergence, which, instead, does not follow from convergence in the product topology, as the well known example of Rubinstein (1989) demonstrates. Finally, if the implication from (a) to (b) holds for every game $G$ and action $a_i$ of player $i$ in $G$, then the implication from (b) to (a) also holds (Dekel, Fudenberg, and Morris, 2006, Corollary 1).

If we strengthen Definition 1 to require the rate of convergence $N$ to be independent of the game $G$ (in all games with uniformly bounded payoffs), we then obtain the following definition. Given a game $G = (A_i, g_i)_{i \in I}$, write $|G| = \max_i \max_j |g_i|$.

**Definition 2** (Uniform strategic topology). A sequence of types $t^n_i$ converges uniform-strategically to a type $t_i$ if for every payoff bound $M > 0$ there exist positive integers $(N_\varepsilon)_{\varepsilon > 0}$ such that for every game $G$ with $|G| \leq M$ and every action $a_i$ of player $i$ in $G$, the following conditions are equivalent:

(a) $a_i$ is rationalizable for $t_i$ in $G$;

(b) for every $\varepsilon > 0$ and $n \geq N_\varepsilon$, $a_i$ is $\varepsilon$-rationalizable for $t^n_i$ in $G$.

The uniform strategic topology is the topology of uniform strategic convergence on $T_i$.

We proceed with the characterizations of the strategic and the uniform-strategic topologies in terms of beliefs. We begin with the uniform-strategic topology, as its characterization takes a simpler form.

### 3.1 Characterization of the Uniform Strategic Topology

To characterize the uniform strategic topology, we use a notion of convergence of types under which the rate of convergence is uniform across the levels of the belief hierarchy. In order to
define this uniformity, we first need to fix a distance on the space of \( k \)-order beliefs. We use the Prohorov distance, which metrizes the topology of weak convergence of probability measures.

For each integer \( k \geq 1 \), we define recursively a distance \( d^k_i \) on \( \mathcal{T}_i \) as the Prohorov distance over \( k \)-order beliefs assuming that the space of \( (k - 1) \)-order beliefs of player \(-i\) is endowed with the distance \( d^{k-1}_{-i} \). Thus, for each player \( i \), we set \( d^0_i \equiv 0 \) and, for each integer \( k \geq 0 \) and types \( s_i \) and \( t_i \),

\[
d^{k+1}_i(s_i, t_i) = \inf \{ \delta > 0 : \mu_i(E | t_i) \leq \mu_i(E^{\delta,k}_i | s_i) + \delta \text{ for each measurable } E \subseteq \Theta \times \mathcal{T}_{-i} \},
\]

where

\[
E^{\delta,k}_i = \left\{ (\theta, s_{-i}) \in \Theta \times \mathcal{T}_{-i} : d^k_{-i}(s_{-i}, t_{-i}) < \delta \text{ for some } t_{-i} \text{ with } (\theta, t_{-i}) \in E \right\}.
\]

We then consider the following notion of uniform convergence, introduced in Chen, Di Tillio, Faingold, and Xiong (2010).

**Definition 3** (Uniform weak convergence). A sequence of types \( t^n_i \) converges \textit{uniform-weakly} to a type \( t_i \) if

\[
d^{uw}_i(t^n_i, t_i) \equiv \sup_{k \geq 1} d^k_i(t^n_i, t_i) \to 0 \quad \text{as} \quad n \to \infty.
\]

Thus, uniform weak convergence is the uniform counterpart of product convergence when the topology of weak convergence of \( k \)-order beliefs is metrized by the Prohorov distance. In Chen, Di Tillio, Faingold, and Xiong (2010), we showed that uniform-weak convergence implies uniform-strategic convergence. Here we prove the reverse implication, thus establishing the equivalence:

**Theorem 1.** A sequence of types converges uniform-strategically if and only if it converges uniform-weakly.

The proof of this and all other results is presented in Appendix A.

Ever since Rubinstein’s (1989) seminal paper, misspecifications of higher-order beliefs have been recognized to have a potentially large impact on strategic predictions. The systematic treatment of Weinstein and Yildiz (2007) exposed the pervasiveness of this sensitivity by showing that the phenomenon is not peculiar to the Electronic Mail game, and hence advocated wider scrutiny of the assumptions one makes about the players’ subjective beliefs. Theorem 1 quantifies the exact impact of such assumptions (uniformly over games) by identifying the appropriate measure of proximity of hierarchies of beliefs. In effect, the role of the Prohorov distance in the definition of uniform weak convergence, and hence in our characterization result, turns out to be nontrivial. For any distance that metrizes the topology of weak convergence of probability measures, one

---

Viewed as a distance on \( \mathcal{T}_i \), \( d^k_i \) is only a pseudo-distance—as opposed to a standard distance—, since there exist distinct types with the same \( k \)-order beliefs (and hence different \( \ell \)-order beliefs, for some \( \ell > k \)).
can define an associated uniform distance over infinite hierarchies of beliefs. However, these distances may generate different topologies over infinite hierarchies, even though the induced topologies over $k$-order beliefs coincide for each finite $k$, as shown in an example in Chen, Di Tillio, Faingold, and Xiong (2010, Section 5.2). Theorem 1 identifies one of these uniform distances that ultimately characterizes the uniform-strategic topology.

Theorem 1 serves as a benchmark for our characterization of the strategic topology in the next section, which is also based on uniform convergence across the orders of the hierarchy of beliefs. Uniform weak convergence requires proximity of beliefs concerning all events in the universal type space. As will soon become apparent, relaxing this requirement is the key to our characterization of the strategic topology.

### 3.2 Characterization of the Strategic Topology

We begin with a definition that plays a central role in our characterization.

**Definition 4 (Frames)**. A frame is a profile $\mathcal{P} = (\mathcal{P}_i)_{i \in I}$, where each $\mathcal{P}_i$ is a finite measurable partition of $\mathcal{T}_i$, such that for each $s_i, t_i \in \mathcal{T}_i$,

$$
\mu_i(\theta \times E | s_i) = \mu_i(\theta \times E | t_i) \quad \forall \theta \in \Theta, \forall E \in \mathcal{P}_{-i} \implies s_i \in \mathcal{P}_i(t_i). \tag{18}
$$

To interpret this definition epistemically, note that any profile of partitions induces a coarsening of the canonical information structure of the universal type space, as follows. Given a profile of partitions $\mathcal{P} = (\mathcal{P}_i)_{i \in I}$ (not necessarily a frame), say that a type $t_i$ knows an event $E \subseteq \mathcal{T}_i$ (relative to $\mathcal{P}$) if $\{s_i \in \mathcal{T}_i : \mu_i(\theta \times F | s_i) = \mu_i(\theta \times F | t_i) \forall \theta \in \Theta, \forall F \in \mathcal{P}_{-i}\} \subseteq E$. Thus, player $i$ knows his beliefs about $\Theta \times \mathcal{P}_{-i}$ (positive introspection), and knows nothing beyond the implications of that knowledge (hence the coarseness of the model).\footnote{Following standard notation, $\mathcal{P}_i(t_i)$ designates the atom of $\mathcal{P}_i$ containing $t_i$.} It is then readily verified that $\mathcal{P}$ is a frame if and only if the coarse information model thus defined is “epistemically closed”: every event concerning player $-i$ that player $i$ can reason about is either known to be true or known to be false by player $i$.\footnote{In other words, this is the coarsest knowledge structure that is consistent with positive introspection when each player $i$ is able to reason only about events in $2^\Theta \otimes \mathcal{P}_{-i}$.} The violation of this condition entails a pathological epistemic model: there is some player $i$ who can reason about some event $E$ contained in $\mathcal{T}_{-i}$ that cannot be interpreted as an event concerning player $-i$, because player $-i$ cannot possibly know whether event $E$ obtains.

The notion of frame is key to our characterization, so it will be useful to go over a few examples to illustrate the definition. We begin by describing a general procedure for constructing a new frame from a given frame. We will then make use of the procedure to discuss three canonical examples of frames.

\footnote{That is, either player $-i$ knows the event, or he knows its complement.}
Given a frame $\mathcal{P}$ and a finite measurable partition $\Pi_i$ of the finite-dimensional simplex $\Delta(\Theta \times \mathcal{P}_{-i})$, define the partition on $\mathcal{T}_i$ induced by $\Pi_i$, written $\mathcal{T}_i / \Pi_i$, as follows: any two types of player $i$ belong to the same element of $\mathcal{T}_i / \Pi_i$ if and only if their beliefs over $\Theta \times \mathcal{P}_{-i}$ belong to the same element of $\Pi_i$. The following lemma is straightforward from the definitions:

**Lemma 2.** Each $\mathcal{T}_i / \Pi_i$ is a measurable partition of $\mathcal{T}_i$, and the join $(\mathcal{P}_i \vee (\mathcal{T}_i / \Pi_i))_{i \in I}$ is a frame.\(^{21}\)

We now present the examples.

**Example 1** (Finite-order frames). A *finite-order frame* is a frame whose atoms are $k$-order measurable events, for some integer $k \geq 1$. For instance, any profile of first-order measurable partitions is a (first-order) frame, as it can be readily verified from Definition 4. Examples of higher order frames can be constructed by successive application of Lemma 2 beginning with an arbitrary profile of first-order measurable partitions. For instance, given a $\theta_0 \in \Theta$ consider the following profile of first-order measurable bi-partitions:

$$\mathcal{P}_i = \left\{ \{t_i : \mu_i(\theta_0|t_i) \in \mathbb{Q}\}, \{t_i : \mu_i(\theta_0|t_i) \notin \mathbb{Q}\} \right\}, \quad i \in I,$$

where $\mathbb{Q}$ is the set of rational numbers. Then, consider the bi-partition $\Pi_1$ of the simplex $\Delta(\Theta \times \mathcal{P}_2)$ into the set

$$\left\{ q \in \Delta(\Theta \times \mathcal{P}_2) : q(\theta_0, \{t_2 : \mu_2(\theta_0|t_2) \in \mathbb{Q}\}) \geq 1/2 \right\}$$

and its complement. Thus, the join $\mathcal{P}_1 \vee (\mathcal{T}_1 / \Pi_1)$ partitions $\mathcal{T}_1$ into four second-order measurable events, according to whether or not a type $t_1$ satisfies each of the following two conditions:

$$\mu_1(\theta_0|t_1) \in \mathbb{Q}, \quad \mu_1 \left( \theta_0 \times \{t_2 : \mu_2(\theta_0|t_2) \in \mathbb{Q}\} \right| t_1 \right) \geq 1/2.$$

The profile $(\mathcal{P}_1 \vee (\mathcal{T}_1 / \Pi_1), \mathcal{P}_2)$ is an example of a second-order frame.\(^\dagger\)

**Example 2** (Common belief frames). Let $\mathbf{p} = (p_1, p_2) \in (0, 1]^2$ and a subset $E \subset \Theta$. The profile of bi-partitions $\mathcal{P}_i = \{C^\mathbf{P}_i(E), \mathcal{T}_i \setminus C^\mathbf{P}_i(E)\}$, $i \in I$, is a frame. Indeed, if any two types of player $i$ agree on the probabilities over $\Theta \times \mathcal{P}_{-i}$, then they must agree on the probability of the event $E \times C^\mathbf{P}_{-i}(E)$. Then, either both types assign probability at least $p_i$ to $E \times C^\mathbf{P}_{-i}(E)$, in which case both types belong to $C^\mathbf{P}_i(E)$ (by Lemma 1), or both types assign probability less than $p_i$ to $E \times C^\mathbf{P}_{-i}(E)$, in which case both types belong to the complement of $C^\mathbf{P}_i(E)$ (again, by Lemma 1).

More generally, given any frame $\mathcal{P}$ and any event $E \subseteq \Omega$ that is $\mathcal{P}$-measurable,\(^{22}\) the join between $\mathcal{P}_i$ and $\{C^\mathbf{P}_i(E), \mathcal{T}_i \setminus C^\mathbf{P}_i(E)\}$ is a frame, called a *common belief frame*.\(^\dagger\)

---

\(^{21}\)Recall that the join of a pair of partitions, denoted by the symbol $\vee$, is the coarsest partition that is finer than both partitions in the pair.

\(^{22}\)This means that $E$ is measurable with respect to the algebra $2^\Theta \otimes \mathcal{P}_1 \otimes \mathcal{P}_2$ on $\Omega$. 

13
Example 3 (Strategic frames). Given $\varepsilon \geq 0$ and a game $G = (A_i, g_i)_{i \in I}$, the $\varepsilon$-strategic frame associated with $G$ is the profile

$$\mathcal{P}_i = \{ [B_i] : \emptyset \neq B_i \subseteq A_i \}, \quad i \in I,$$

where

$$[B_i] = \{ t_i : R_i(t_i, G, \varepsilon) = B_i \}.$$

(For $\varepsilon = 0$ we call it simply the strategic frame of $G$.) To check that the above is indeed a frame, suppose that $s_i$ and $t_i$ are two arbitrary types of player $i$ that have the same beliefs concerning all the events of the form $\theta \times [B_{-i}]$. Let us show that $s_i$ and $t_i$ have the same set of $\varepsilon$-rationalizable actions in $G$. If $a_i \in R_i(t_i, G, \varepsilon)$ then, by definition, there is a conjecture $v \in \Delta(\Theta \times \mathcal{T}_{-i} \times A_{-i})$ that satisfies $\text{marg}_{\Theta \times \mathcal{T}_{-i}} v = \mu_i(t_i), v\left(\text{graph} \ R_{-i}(\cdot, G, \varepsilon)\right) = 1$ and $a_i \in BR_i\left(\text{marg}_{A_{-i} \times \Theta} v, G, \varepsilon\right)$. Then, define a conjecture $\tilde{v} \in \Delta(\Theta \times \mathcal{T}_{-i} \times A_{-i})$ for type $s_i$ as follows: for each $\theta \in \Theta$, $a_{-i} \in A_{-i}$ and measurable $E \subseteq \mathcal{T}_{-i}$,

$$\tilde{v}(\theta \times E \times a_{-i}) = \sum_{B_{-i}} \frac{v(\theta \times [B_{-i}] \times a_{-i})}{v(\theta \times [B_{-i}] )} \mu_i(\theta \times (E \cap [B_{-i}])|s_i),$$

where the summation ranges over all $B_{-i} \subseteq A_{-i}$ such that $\mu_i(\theta \times (E \cap [B_{-i}])|s_i) > 0$. Notice that $\tilde{v}$ is well defined, because whenever $\mu_i(\theta \times (E \cap [B_{-i}])|s_i) > 0$ we must also have $v(\theta \times [B_{-i}]) > 0$, since

$$v(\theta \times [B_{-i}]) = \mu_i(\theta \times [B_{-i}]|t_i) = \mu_i(\theta \times [B_{-i}]|s_i). \quad (1)$$

By construction, we have $\text{marg}_{\Theta \times \mathcal{T}_{-i}} \tilde{v} = \mu_i(s_i)$. Also, the condition $v\left(\text{graph} \ R_{-i}(\cdot, G, \varepsilon)\right) = 1$ implies that for every $\theta \in \Theta$, $a_{-i} \in A_{-i}$ and $B_{-i} \subseteq A_{-i}$,

$$\tilde{v}(\theta \times [B_{-i}] \times a_{-i}) > 0 \implies v(\theta \times [B_{-i}] \times a_{-i}) > 0 \implies a_{-i} \in B_{-i}.$$

Hence, $v\left(\text{graph} \ R_{-i}(\cdot, G, \varepsilon)\right) = 1$. Finally, (1) above implies $\text{marg}_{A_{-i} \times \Theta} \tilde{v} = \text{marg}_{A_{-i} \times \Theta} v$. Thus, $a_i \in BR_i\left(\text{marg}_{A_{-i} \times \Theta} \tilde{v}, G, \varepsilon\right)$, and therefore $a_i \in R_i(s_i, G, \varepsilon)$. We have thus shown that $R_i(t_i, G, \varepsilon) \subseteq R_i(s_i, G, \varepsilon)$, and the opposite inclusion can be proved by interchanging the roles of $s_i$ and $t_i$ in the argument above. This proves that the $\varepsilon$-strategic frame is indeed a frame.

We emphasize that not every frame is the strategic frame of a game. For instance, in a strategic frame, each player’s partition must contain an atom that is open in the product topology, namely, any atom consisting of types whose set of rationalizable actions is minimal (w.r.t. set inclusion). General frames, however, need not contain open sets. The first-order frame in Example 1 illustrates this fact.

---

23That such an atom is product-open follows from minimality and the upper hemi-continuity of the rationalizable correspondence.
Turning to the characterization of strategic convergence, we introduce a notion of uniform weak convergence of types relative to a fixed frame \( \mathcal{P} \). For each player \( i \), set \( d^0_{i, \mathcal{P}} = 0 \) and, for each integer \( k \geq 0 \) and types \( s_i \) and \( t_i \), define
\[
d^k_{i, \mathcal{P}}(s_i, t_i) = \inf \left\{ \delta > 0 : \mu_i(E | t_i) \leq \mu_i\left( E_{\mathcal{P}}^k | s_i \right) + \delta \quad \forall E \in 2^\Theta \otimes \mathcal{P}_i \right\},
\]where
\[
E_{\mathcal{P}}^k = \left\{ (\theta, s_{-i}) \in \Theta \times \mathcal{T}_{-i} : d^k_{i, \mathcal{P}}(s_{-i}, t_{-i}) < \delta \quad \text{for some} \ t_{-i} \text{ with} \ (\theta, t_{-i}) \in E \right\}.
\]
Thus, the definition of \( d^k_{i, \mathcal{P}} \) is similar to that of \( d^k_i \), but restricts the events for which the proximity is measured to those in the frame \( \mathcal{P} \).

**Definition 5** (Uniform weak convergence on frames). A sequence of types \( t^n_i \) converges to a type \( t_i \) uniform-weakly on a frame \( \mathcal{P} \) if
\[
d^{uw}_{i, \mathcal{P}}(t^n_i, t_i) \overset{\text{def}}{=} \sup_{k \geq 1} d^k_{i, \mathcal{P}}(t^n_i, t_i) \rightarrow 0 \quad \text{as} \quad n \rightarrow \infty.
\]

With this definition in place, we are ready to state our characterization.

**Theorem 2.** A sequence of types converges strategically if and only if it converges uniform-weakly on every frame.

The theorem has conceptual and practical significance. First, the result deepens our understanding of the belief underpinnings of strategic robustness by characterizing, in terms of the primitives of the model (hierarchies of beliefs), the class of all perturbations to which the predictions of rationalizability are robust.

Second, as in Theorem 1, the result draws attention to a particular form of uniform convergence across the levels of the belief hierarchy as a condition for robustness. While it is expected that some form of uniform convergence should play a role, it is much less clear at the outset what kind of uniformity would ultimately lead to a characterization. For instance, one might expect that the strategically relevant notion of uniform convergence were the one that requires every event that is common belief for the limit type to remain arbitrarily close to an event that is approximately common belief for the types that are sufficiently far in the tail of the sequence. Indeed, an ex ante variation of this condition characterizes the robust perturbations for Bayesian equilibrium in countable common prior type spaces, as shown in the early papers of Monderer and Samet (1996) and Kajii and Morris (1998). However, this is not the case in our framework, for that notion of convergence turns out to be equivalent to uniform weak convergence on common belief frames.

---

\( ^{24} \)This restriction makes \( d^k_{i, \mathcal{P}} \) only a pre-distance, that is, it satisfies \( d^k_{i, \mathcal{P}}(s_i, t_i) \geq 0 \) and \( d^k_{i, \mathcal{P}}(t_i, t_i) = 0 \), but it fails symmetry and the triangle inequality.
(c.f. Example 2), whereas the characterization above requires convergence on all frames, and the latter turns out to be a stronger condition.

Third, the theorem highlights the role of frames as the coarse information structures that are relevant for strategic convergence. The role of frames in the “only if” direction is intuitive. Given a profile of partitions that is not a frame, there is always a player $i$ who can reason about some event $E$ that concerns player $-i$ such that player $-i$ cannot know whether or not $E$ obtains. But since the strategic behavior of a player can only depend on events that the player knows, it is intuitive that failure of uniform weak convergence on a profile of partitions that is not a frame need not imply failure of strategic convergence. As for the “if” direction, the role of frames is more mechanical. If a sequence $t^n_i$ converges uniform weakly on all frames, then, given an arbitrary game, the sequence must converge uniform-weakly on the strategic frame generated by that game. This fact, combined with the continuity of the $\varepsilon$-best-reply correspondence in the Prohorov metric, leads naturally to an induction argument (over the levels of the hierarchy) that proves the strategic convergence of $t_i$, as in the proof presented in Appendix A.3.

Fourth, the theorem leads to a connection between the strategic topology and the early literature on robustness mentioned above, and in particular to the notion of common $p$-beliefs, which plays a prominent role in that literature. In the next section, we use Theorem 2 to show that strategic convergence implies an interim analogue of the mode of convergence based on common $p$-beliefs of the early literature. We also present a striking example that shows that the converse fails.

Fifth, the characterization enables the genericity analysis that we carry out in Section 4, where we revisit, and reverse, two important genericity results of the recent literature (due to Ely and Pêski (2011) and Lipman (2003)), which were carried out in the product topology.

Finally, there are instances when the characterization has practical significance. To illustrate, we present Example 4 below, where we describe a case in which it is particularly simple to apply the characterization to prove that a sequence converges strategically, even though the sequence does not converge uniform weakly. Nonetheless, we do not maintain that this is a general feature of the characterization, that is, we do not claim that our characterization has any computational advantages over the definition of strategic convergence in general. In terms of computational complexity, checking uniform weak convergence in every frame appears to be as hard as checking convergence of rationalizable behavior in every game. The main point of our exercise remains to express conditions for robustness in terms of primitives.

**Example 4** (A sequence that converges uniform-weakly on all frames). To build our example, we need a preliminary definition. Fix two distinct states $\theta_0, \theta_1 \in \Theta$ and define the Dirac type space (based on $\{\theta_0, \theta_1\}$) as the abstract type space $(X_i, \phi_i)_{i \in I}$, where each $X_i = \{0, 1\}^{\mathbb{N}}$ (the

---

25 The precise meanings of “reason about” and “know”, relative to the coarse information model induced by a profile of partitions, is explained in the paragraph that follows Definition 4.
space of all infinite sequences of 0’s and 1’s) and for each type \( x_i = (x_{i1}, x_{i2}, \ldots) \), the belief \( \phi_i(x_i) \) assigns probability one to the singleton \( \{ (\theta_{x_{i1}}, \ell_{-i}(x_i)) \} \), where \( \ell_{-i} \) is the left-shift operator: \( \ell_{-i}(x_{i1}, x_{i2}, \ldots) = (x_{i2}, x_{i3}, \ldots) \). Thus, the hierarchy of beliefs of a Dirac type \( x_i = (x_{i1}, x_{i2}, \ldots) \) assigns probability one to state \( \theta_{x_{i1}} \), probability one to \(-i\) assigning probability one to \( \theta_{x_{i2}} \), probability one to \(-i\) assigning probability one to \( i \) assigning probability one to \( \theta_{x_{i3}} \), and so on.

We now present an example of a sequence of Dirac types, \( s^n_i \), for which it will be particularly simple to prove uniform weak convergence on all frames, even though \( s^n_i \) will not converge uniform weakly. For each positive integer \( n \), let \( b_n \) be the finite sequence of length \( 2n \) comprising \( n \) zeroes followed by \( n \) ones. Thus, \( b_1 = (0, 1), b_2 = (0, 0, 1, 1) \), and so on. Let \( t^n_i \) and \( s^n_i \) be the Dirac types of player \( i \) such that \( t^n_i = (b_n, b_{n+1}, \ldots) \) and \( s^n_i = (b_1, \ldots, b_{n-1}, 0, 0, 0, \ldots) \). It can be readily verified that \( d^{n \leftarrow} k^{n} (s^n_i, t^1_i) \) equals zero for \( k \leq n^2 \) and equals one for \( k > n^2 \). Therefore, the sequence \( s^n_i \) converges to \( t^1_i \) in the product topology, but not uniform-weakly.

Let us show that \( s^n_i \) converges to \( t^1_i \) uniform weakly on every frame. First, note that \( \ell_{-i}(t^n_i) \) and \( \ell_{-i}(s^n_i) = (0, 0, 0, \ldots) \) share the same first \( n-1 \) coordinates (a sequence of \( n-1 \) zeroes), hence \( d^{n \leftarrow} i^{n-1} (\ell_{-i}(t^n_i), \ell_{-i}(s^n_i)) = 0 \). It follows that the sequence \( \ell_{-i}(t^n_i) \) converges to \( \ell_{-i}(s^n_i) \) in the product topology. Next, fix an arbitrary frame \( \mathcal{P} \). Let \( \mathcal{P}_\rightarrow -i \subseteq \mathcal{P}_{-i} \) be the set of all elements of \( \mathcal{P}_{-i} \) that contain infinitely many types from the sequence \( \ell_{-i}(t^n_i) \). Thus, for every \( n \) and \( P_{-i} \in \mathcal{P}_\rightarrow -i \), there is a type in \( P_{-i} \) whose first \( n-1 \) coordinates are all zeroes. It follows that, for every \( k \) and \( P_{-i} \in \mathcal{P}_\rightarrow -i \), we have \( \ell_{-i}(s^n_i) \in (P_{-i})_{\mathcal{P}}^{0,k} \) and, therefore, \( \mu_i(\theta_0 \times (P_{-i})_{\mathcal{P}}^{0,k} | s^n_i) = 1 \). Furthermore, there exists \( N \) such that, for every \( n \geq N \), there exists \( P_{-i} \in \mathcal{P}_\rightarrow -i \) such that \( \ell_{-i}(t^n_i) \in P_{-i} \) and, therefore, \( \mu_i(\theta_0 \times P_{-i} | t^n_i) = 1 \). It follows that \( d^{k \leftarrow} i,\mathcal{P} (s^n_i, t^n_i) = 0 \) for every \( k \geq 1 \) and \( n \geq N \). Finally, since \( s^n_i = (b_1, \ldots, b_{n-1}, s^n_1) \) and \( t^n_i = (b_1, \ldots, b_{n-1}, t^n_1) \) have the same first \( 2n(n+1) \) coordinates, a straightforward induction argument shows that \( d^{k \leftarrow} i,\mathcal{P} (s^n_i, t^n_i) = 0 \) for every \( k \geq 1 \) and \( n \geq N \). Thus, for all \( n \geq N \), we have \( \sup_{k \geq 1} d^{k \leftarrow} i,\mathcal{P} (s^n_i, t^n_i) = 0 \), and hence the sequence \( s^n_i \) converges to \( t^n_i \) uniform-weakly on \( \mathcal{P} \). As this is true for every frame \( \mathcal{P} \), we conclude that \( s^n_i \) converges strategically to \( t^n_i \), as claimed.

### 3.3 Convergence in Common Beliefs

Previous work on strategic topologies for Bayesian equilibrium (BE) under common priors (Monderer and Samet, 1996; Kajii and Morris, 1998) has proved equivalences between an ex ante notion of strategic convergence for BE and ex ante notions of convergence based on common beliefs. In this section, we consider the interim version of common belief convergence, prove that it is a necessary condition for convergence in the strategic topology for interim correlated rationalizability, and demonstrate, by means of an example, that it fails to be sufficient. This highlights a fundamental difference between the strategic topologies in the common prior, equilibrium, ex ante framework of Monderer and Samet (1996) and Kajii and Morris (1998) and in our non-common
prior, non-equilibrium, interim framework.

**Definition 6** (Common belief convergence). A sequence of types $t^n_i$ converges in common beliefs to a type $t_i$ if for every $\delta > 0$, every integer $k \geq 1$, every measurable set $E \subseteq \Omega$ and every $p \in [0, 1]^2$ with $t_i \in C_p^i(E)$, there exists $N$ such that for every $n \geq N$, $t^n_i \in C_{p-\delta}^i(E^\delta,k)$.  

To shed light on the definition, an analogy with product convergence is useful. A necessary and sufficient condition for a sequence of types $t^n_i$ to converge to a type $t_i$ in the product topology is that for every $\delta > 0$, every integer $k \geq 1$, every measurable set $E \subseteq \Omega$ and every $p \in [0, 1]^2$ with $t_i \in B_p^i(E)$, there exists $N$ such that for every $n \geq N$, $t^n_i \in B_{p-\delta}^i(E^\delta,k)$. There is thus a formal sense in which convergence in common beliefs is the “common” analogue of product convergence.

Notice that common belief convergence implies product convergence, because setting $p = (p, 0)$ yields $B_p^i = C_i^p$. As for the connection with strategic convergence, we show:

**Theorem 3.** Strategic convergence implies convergence in common beliefs.

This result is useful for three reasons. First, it improves our understand of the strategic topology by providing an easy-to-interpret “lower bound” on how strong strategic convergence is. Second, the result (coupled with the example below), clarifies the relationship between the strategic topology for interim rationalizability on the universal type space and the ex ante strategic topology for BE in common prior, countable type spaces of the early literature on robustness. Third, the result is used in our proofs of the topological genericity results of Section 4).

As mentioned, the converse of Theorem 3 fails to hold:

**Example 5** (Convergence in common beliefs does not imply strategic convergence). We shall exhibit a sequence of types $t^n_i$ that converges in common beliefs to a type $t_1$, but does not converge uniform-weakly on a frame; hence, by Theorem 2, it does not converge strategically either. To construct the sequence, fix $\theta_0 \in \Theta$ and $0 < p < q < 1$. For each player $i$, pick a type $r_i$ that satisfies the following two conditions:

1. $r_i$ assigns probability zero to state $\theta_0$;

2. If we modify the definition to require the equivalence between (a) and (b) to hold only for events $E$ that are closed in the product topology, then the notion of convergence remains the same. Indeed, letting $\overline{E}$ denote the product-topology closure of $E$, we have $C_p^i(\overline{E}) \subseteq C_p^i(E)$ and $E^\delta,k = (\overline{E})^\delta,k$.

27This follows directly from the following two facts: (i) the Mertens-Zamir isomorphism $\mu_i : T_i \to \Delta(\Theta \times T_{-i})$ becomes a homeomorphism when each $T_{-i}$ is endowed with the product topology and $\Delta(\Theta \times T_{-i})$ is endowed with the topology of weak convergence (as remarked in footnote 14); (ii) the Prohorov metric on $\Delta(\Theta \times T_{-i})$ metrizes the topology of weak convergence.
(ii) for every product-closed proper subset $E \subset \Omega$ and $\eta > 0$, $r_i \notin C_i^{n\bf{1}}(E)$.$^{28}$

Let $s_i$ and $t_i$ be the types who assign probability one to $\theta_0$ and whose beliefs about the other player’s types are as specified in Figure 1 below.

$$
\begin{align*}
&s_1 \quad p \quad s_2 \quad p \quad t_1 \\
&t_1 \quad q \quad t_2 \quad p \quad r_1 \\
&s_1 \quad p \quad s_2 \quad p \quad r_2 \\
&\quad 1-q \quad 1-p \quad 1-p \quad 1-p
\end{align*}
$$

Figure 1: The types $s_i$ and $t_i$.

Since $r_1$ and $r_2$ satisfy property (ii) above, for every $p \in (0, 1]^2$, every product-closed proper subset $E \subset \Omega$, and every $i \in I$,

$$
t_i \in C_i^p(E) \iff p \leq (p, p) \text{ and } E \supseteq \{s_1, t_1\} \times \{s_2, t_2\}.
$$

(2)

In particular, no nontrivial event is common $(q, p)$-belief at $t_1$. We exploit this fact to construct the sequence $t_1^n$ so that the probability assigned to $s_1, t_2$ drops to $q - \Delta > p$ under $t_1^n$, while ensuring that all events commonly $p$-believed at $t_1$ for some $p \in (0, 1]^2$ remain so at $t_1^n$. Because the probability assigned to $(\theta_0, t_2)$ under $t_1^n$ and $t_1$ differ by a positive $\Delta$, we are able to construct a frame on which $t_1^n$ fails to converge to $t_1$ uniform-weakly.

The construction of the sequence mimics the structure in Figure 1. Fix $0 < \Delta < q - p$ and for each player $i$ define $s_i^n$ and $t_i^n$ as follows: let $t_1^1 = r_1$ and, for each $n \geq 1$, let $s_2^n$, $s_1^n$, $t_2^n$ and $t_1^{n+1}$ be the types who assign probability one to $\theta_0$ and whose beliefs about the other player’s types are as described in Figure 2 below.

$$
\begin{align*}
&s_1 \quad p \quad s_2 \quad p \quad t_1^n \\
&t_1^{n+1} \quad \Delta \quad t_2^n \\
&t_2^n \quad p \quad s_1^n \quad p \quad s_2^n \quad p \quad t_1^n \\
&\quad 1-q \quad 1-p \quad 1-p \quad 1-p \quad 1-p
\end{align*}
$$

Figure 2: The sequences of types $s_i^n$ and $t_i^n$.

The sequence $t_1^n$ converges to $t_1$ in common beliefs. To see why, first note that $t_1^n \to t_1$ in the product topology: by the construction in Figures 1 and 2, $s_2^1$ has the same first-order belief

$^{28}$Types that satisfy these conditions exist. Ely and Peski (2011, Theorem 1) show that the types that satisfy property (ii) are precisely those types to which product convergence is equivalent to strategic convergence, called regular types. They show that the set of regular types is a residual subset of the universal type space (in the product topology), in particular a non-empty set. As for condition (i), note that any type of player $i$ that assigns probability one to some $(\theta, u_{-i})$, where $u_{-i}$ is a type of player $-i$ that satisfies property (ii), must also satisfy property (ii). This implies the existence of types satisfying both (i) and (ii).
as \( s_2 \), hence \( s_1^1 \) has the same second-order belief as \( s_1 \), which implies \( t_1^1 \) has the same third-order belief as \( t_2 \), and so forth. Second, given an arbitrary \( \varepsilon > 0 \), by the construction in Figure 2 and the product-convergence \( t_1^n \to t_1 \), for each integer \( k \geq 1 \) we have \( t_1^n \in B_1^{q-\Delta} (\theta_0 \times \{t_1^1\}^\delta_k \times t_2) \) for all \( n \) large enough. Since \( t_2 \in C_2^{(p,p)} (\theta_0 \times \{s_1, t_1\} \times \{s_2, t_2\}) \) and \( q - \Delta \geq p \), it follows that for all \( n \) large enough,

\[
t_1^n \in B_1^p (\theta_0 \times \{t_1^1\}^\delta_k \times C_2^{(p,p)} (\theta_0 \times \{s_1, t_1\} \times \{s_2, t_2\})) \subseteq C_1^{(p,p)} ((\theta_0 \times \{s_1, t_1\} \times \{s_2, t_2\})^\delta_k).
\]

It follows, by (2) and footnote 26, that \( t_1^n \to t_1 \) in common beliefs, as claimed.

To conclude the example, it remains to show:

**Claim 1.** There is a frame \( P \) such that \( t_1^n \not\to t_1 \) uniform-weakly on \( P \).

This claim is proved in Appendix A.5. Here, to provide intuition, we give a proof of the weaker but closely related statement that \( t_1^n \) does not converge to \( t_1 \) uniform-weakly. In effect, since \( t_1^1 \) assigns probability zero to \( \theta_0 \), we have \( d_1^2(t_1^1, t_1) = 1 \). Then, by the constructions in Figures 1 and 2, the fourth-order Prohorov distance between \( t_2^2 \) and \( t_2 \) must also be one, that is, \( d_2^4(t_1^1, t_2) = 1 \). Therefore,

\[
\mu_1 ((\theta_0 \times t_2)^{\Delta,4} \mid t_1^2) = \mu_1 ((\theta_0 \times t_2) \mid t_1^2) = q - \Delta = \mu_1 (\theta_0 \times t_2 | t_1) - \Delta.
\]

hence \( d_1^2(t_1^2, t_1) \geq \Delta \). Continuing in the same fashion it can be readily verified that \( d_1^3(t_1^3, t_1) \geq \Delta, d_1^{13}(t_1^4, t_1) \geq \Delta \), and so forth. That is, \( d_1^{4n-3}(t_1^n, t_1) \geq \Delta \) for all \( n \), and hence \( t_1^n \not\to t_1 \) uniform-weakly, as claimed.

This example, combined with Theorem 3, shows that strategic convergence is strictly stronger than convergence in common beliefs. However, when the limit type is assumed a finite type—a type that belongs to a finite type space—we show that convergence in common beliefs implies uniform-strategic convergence. We thus have:

**Theorem 4.** Given a finite type \( t_i \) and a sequence of (possibly infinite) types \( t_i^n \), the following statements are equivalent:

(a) \( t_i^n \to t; \) uniform-weakly;

(b) \( t_i^n \to t_i \) uniform-strategically;

(c) \( t_i^n \to t_i \) strategically;

(d) \( t_i^n \to t_i \) uniform-weakly on every frame;

(e) \( t_i^n \to t_i \) in common beliefs.
4 Genericity Analysis

We apply our characterizations to establish topological genericity results on the universal type space concerning critical types and common prior types. We also provide analogous results for the measure-theoretic genericity notions of finite shyness and finite prevalence.29

4.1 Genericity of Critical Types

In a recent paper, Ely and Pęski (2011) define critical types as those types to which product convergence fails to imply strategic convergence. That is, a type $t_i$ is critical if there is a sequence of types $t^n_i$ that converges to $t_i$ in the product topology such that, for some $\varepsilon > 0$ and some game $G$, $R(t_i, G) \not\subseteq R(t^n_i, G, \varepsilon)$ infinitely often. Thus, from the point of view of robustness, the critical types are the problematic types.

How “large” is the set of critical types? Ely and Pęski (2011) provide two results that address this question. The first one is their insightful characterization of critical types in terms of common beliefs:

Ely and Pęski (2011, Theorem 1). A type $t_i$ is critical if and only if $t_i \in C^p(E)$ for some $p > 0$ and some product-closed proper subset $E_i \subset T_i$.

It follows that all finite types are critical, and so are almost all types that belong to a type space where there is a common prior (Ely and Pęski, 2011, Theorems 4 and 5). Thus, the set of critical types is “large” in the sense that critical types are pervasive: virtually all types used in applications are critical types.

An alternative approach to answer the question is based on topological genericity. There is, however, a tension between topological genericity in the product topology and the pervasiveness of critical types. Indeed, Ely and Pęski (2011) show that the set of critical types is topologically small (under the product topology):

Ely and Pęski (2011, Theorem 2). The set of critical types is meager under the product topology on $T_i$ (i.e., it is contained in a countable union of nowhere dense sets).

We show, however, that this tension disappears when one considers either genericity under the strategic topology, or genericity under the measure-theoretic notion of finite prevalence:

Theorem 5. The set of critical types is open and dense in the universal type space under the strategic topology. Furthermore, the set of critical types is finitely prevalent.

29Finite shyness strengthens the notion of shyness, originally proposed by Christensen (1974). See Anderson and Zame (2001) for details.
Finally, consider the following variation of the notion of critical types: a type $t_i$ is *uniformly critical* if there is some sequence that converges to $t_i$ in the product topology but fails to converge uniform-strategically. An immediate implication of our Theorem 1 is that all types are uniformly critical, since for every type $t_i$ in the universal type space there is always a sequence that converges to $t_i$ in the product topology but does not converge uniform-weakly.\footnote{To prove this, for each player $i$ and integer $k \geq 1$ we construct two measurable functions $\phi^k_i : \mathcal{T}_i \to \mathcal{T}_i$ and $\psi^k_i : \mathcal{T}_i \to \mathcal{T}_i$ that satisfy $d_{t_i}^{k-1}(t_i, \phi^k_i(t_i)) = d_{t_i}^{k-1}(t_i, \psi^k_i(t_i)) = 0$ for all $t_i \in \mathcal{T}_i$, and $(\phi^k_i(\mathcal{T}_i))^{1, k} \cap \psi^k_i(\mathcal{T}_i) = \emptyset$. To define these functions for $k = 1$, pick any $\theta \in \Theta$ and $s_j, s'_j \in \mathcal{T}_i$ such that $\mu_i(\theta|s_j) = 1$ and $\mu_i(\theta|s'_j) = 0$, and define $\phi^1_i(t_i) = s_j$ and $\psi^1_i(t_i) = s'_j$ for all $t_i \in \mathcal{T}_i$. Proceeding recursively, assume that the functions $\phi^k_i$ and $\psi^k_i$ are defined for $k \geq 1$, and define $\phi^{k+1}_i$ and $\psi^{k+1}_i$ as follows: for each $t_i \in \mathcal{T}_i$, $\theta \in \Theta$ and measurable $E_{-i} \subseteq \mathcal{T}_{-i}$, $\mu_i(\theta \times E_{-i}|\phi^{k+1}_i(t_i)) = \mu_i(\theta \times (\phi^{k+1}_i)^{-1}(E_{-i})|t_i)$ and $\mu_i(\theta \times E_{-i}|\psi^{k+1}_i(t_i)) = \mu_i(\theta \times (\psi^{k+1}_i)^{-1}(E_{-i})|t_i)$.
}

### 4.2 Genericity of Common Prior Types

The common prior assumption, according to which the players’ beliefs are generated by a single probability distribution on the state space, is a cornerstone of virtually all models of information economics. Recall that a *common prior* on a countable type space $\mathcal{T}_i \subseteq I$ is a probability distribution $\eta \in \Delta(\Theta \times \mathcal{T}_1 \times \mathcal{T}_2)$ such that, for every $i \in I$, $t_i \in \mathcal{T}_i$ and measurable $E \subseteq \Theta \times \mathcal{T}_{-i}$,

$$\eta_i(t_i) = (\text{marg}_{\mathcal{T}_i} \eta)(t_i) > 0 \quad \text{and} \quad \eta(\{(\theta, t_1, t_2) : (\theta, t_{-i}) \in E\})/\eta_i(t_i) = \mu_i(E|t_i).$$

A *common prior type* is a type that belongs to a countable type space that has a common prior.

The widespread use of common prior models, in both theoretical and applied work, begs the question of whether the behavioral implications of the common prior assumption are robust to misspecification errors in the assumed type space. Taking an interim perspective, Lipman (2003) shows that (finite) common prior types are dense in the product topology, but warns that this result should not be interpreted as a statement that the common prior assumption is without loss of generality: Although every type can be approximated by a common prior type in the product topology, the strategic behavior of that type can be very different from the strategic behavior of any approximating common prior type.

The next result shows that this lack of robustness is a pervasive phenomenon in the universal type space. The denseness result of Lipman (2003) is reversed, once we consider the strategic topology rather than the product topology. Moreover, an analogous conclusion holds when we look at measure-theoretic genericity.

**Theorem 6.** The set of common prior types is nowhere dense in the universal type space under the strategic topology. Moreover, it is finitely shy.
A Appendix

A.1 Properties of ICR

Some of the proofs in the appendix use the characterizations of ICR in terms of iterated elimination of never interim best-replies and of iterated elimination of strongly interim dominated strategies. We review these definitions below.

We begin with the recursive characterization of ICR in terms of iterated elimination of never interim best-replies. Given $\epsilon \geq 0$ and a game $G = (A_i, g_i)_{i \in I}$, for each $i \in I$ and $t_i \in T_i$, let $R_i^0(t_i, G, \epsilon) = A_i$ and, recursively for each $k \geq 1$, let $R_i^k(t_i, G, \epsilon)$ be the set of all $a_i \in A_i$ for which there is a measurable function $\sigma_{-i} : \Theta \times T_{-i} \rightarrow \Delta(A_{-i})$ that satisfies:

$$
\text{supp } \sigma_{-i}(\theta, t_{-i}) \subseteq R_{-i}^{k-1}(t_{-i}, G, \epsilon) \quad \forall (\theta, t_{-i}) \in \Theta \times T_{-i}.
$$

(3)

Then,

$$
R_i(t_i, G, \epsilon) = \bigcap_{k \geq 1} R_i^k(t_i, G, \epsilon).
$$

(See Dekel, Fudenberg, and Morris (2007), Corollary 1, Claim 2.)

For future reference, a measurable function $\sigma_{-i}$ that satisfies (3) is called a $(k - 1)$-order $\epsilon$-rationalizable conjecture; a measurable function $\sigma_{-i}$ such that $\text{supp } \sigma_{-i}(\theta, t_{-i}) \subseteq R_{-i}(t_{-i}, G, \epsilon)$ for every $(\theta, t_{-i}) \in \Theta \times T_{-i}$ is called an $\epsilon$-rationalizable conjecture.

Finally, we review the definition of ICR in terms of iterated elimination of strongly interim dominated actions. For each $i \in I$ and $t_i \in T_i$, let $S_i^0(t_i, G, \epsilon) = A_i$ and, recursively for $k \geq 1$, define $S_i^k(t_i, G, \epsilon)$ as the set of all $a_i \in A_i$ such that for every mixed deviation $\alpha_i \in \Delta(A_i)$ there is a conjecture $\sigma_{-i} : \Theta \times T_{-i} \rightarrow \Delta(A_{-i})$ that satisfies:

$$
\text{supp } \sigma_{-i}(\theta, t_{-i}) \subseteq S_{-i}^{k-1}(t_{-i}, G, \epsilon) \quad \forall (\theta, t_{-i}) \in \Theta \times T_{-i}, \quad \text{and}
$$

$$
\int_{\Theta \times T_{-i}} \left[ g_i(a_i, \sigma_{-i}(\theta, t_{-i}), \theta) - g_i(\alpha_i, \sigma_{-i}(\theta, t_{-i}), \theta) \right] d\mu_i(\theta, t_{-i} | t_i) \geq -\epsilon.
$$

(4)

Then,

$$
R_i^k(t_i, G, \epsilon) = S_i^k(t_i, G, \epsilon),
$$

and thus,

$$
R_i(t_i, G, \epsilon) = \bigcap_{k \geq 1} S_i^k(t_i, G, \epsilon).
$$

(See Chen, Di Tillio, Faingold, and Xiong (2010), Proposition 1.) Likewise, $a_i \in R_i(t_i, G, \epsilon)$ if and only if, for every $\alpha_i \in \Delta(A_i)$, there is a rationalizable conjecture $\sigma_{-i} : \Theta \times T_{-i} \rightarrow \Delta(A_{-i})$ that satisfies (4).
Remark 1. In the above formulations of ICR we have chosen to work with conjectures of the form \( \sigma_{-i} : \Theta \times \mathcal{T}_{-i} \to \Delta(A_{-i}) \), rather than with those of the form \( v \in \Delta(\Theta \times \mathcal{T}_{-i} \times A_{-i}) \), \( \text{marg}_{\Theta \times \mathcal{T}_{-i}} v = \mu_i(t_i) \), as in the definition of ICR given in Section 2.1. These two kinds of conjectures are related by the disintegration formula:

\[
v(\theta \times E_{-i} \times a_{-i}) = \int_{E_{-i}} \sigma_{-i}(\theta, t_{-i}) [a_{-i}] \mu_i(\theta \times dt_{-i} | t_i),
\]

for every \( \theta \in \Theta \), \( a_{-i} \in A_{-i} \) and measurable subset \( E_{-i} \subseteq \mathcal{T}_{-i} \).

### A.2 Proof of Theorem 1

The if direction is proved in Chen, Di Tillio, Faingold, and Xiong (2010). The proof of the only if direction relies on Lemma 3, Corollary 1 and Lemma 4 below.

We begin with some useful definitions and notations. Given a game \( G = (A_i, g_i)_{i \in I} \), say that an action \( a_i^0 \in A_i \) is a zero action for player \( i \) if \( g_i(a_i^0, a_{-i}, \theta) = 0 \) for all \( \theta \) and \( a_{-i} \). An action profile \( a^c = (a_i^c, a_{-i}^c) \) is a coordination pair if \( g_i(a_i^c, a_{-i}^c, \theta) = \max g_i \) for all \( \theta \) and \( i \). (In particular, any action of player \( i \) that is part of a coordination pair is rationalizable for any type of player \( i \).) Finally, we write \( \pi_{t_i, \sigma_{-i}} \in \Delta(A_{-i} \times \Theta) \) to denote the belief of type \( t_i \) over the actions of player \( -i \) and the payoff-relevant states, when he has a conjecture \( \sigma_{-i} : \Theta \times \mathcal{T}_{-i} \to \Delta(A_{-i}) \); i.e.,

\[
\pi_{t_i, \sigma_{-i}}(a_{-i}, \theta) = \int_{\mathcal{T}_{-i}} \sigma_{-i}(\theta, t_{-i}) [a_{-i}] \mu_i(\theta \times dt_{-i} | t_i) \quad \forall (a_{-i}, \theta) \in A_{-i} \times \Theta.
\]

The only if part of the theorem is a direct implication of Lemma 4 below. Lemma 3 and Corollary 1 are intermediate results.

**Lemma 3.** For every \( \varepsilon > 0 \), integer \( k \geq 1 \), player \( j \) and finite set of finite types \( \{t_j, 1, t_j, 2, \ldots, t_j, N\} \subset \mathcal{T}_j \), there is a game \( G = (A_i, g_i)_{i \in I} \) with payoffs in the interval \([-5, 3]\), and a set of actions \( \{a_{j, 1}^*, a_{j, 2}^*, \ldots, a_{j, N}^*\} \subset A_j \), such that:

(i) every player \( i \) has a zero action \( a_i^0 \in A_i \);

(ii) there is a coordination pair \( a^c \in A_1 \times A_2 \) such that \( a_i^c \notin \{a_{i, 1}^*, a_{i, 2}^*, \ldots, a_{i, N}^*\} \) and \( g_i(a_i, a_{-i}^c, \theta) \geq -2 \) for every \( a_i \in A_i \), \( \theta \in \Theta \) and \( i \in I \);

(iii) \( R_i(\cdot, G, \gamma) = R_i^k(\cdot, G, \gamma) \) for every \( i \in I \) and \( \gamma \in [0, \frac{1}{2}] \);

---

31 Given a \( v \) that satisfies \( \text{marg}_{\Theta \times \mathcal{T}_{-i}} v = \mu_i(t_i) \), the disintegration formula only pins down \( \sigma_{-i} \) up to a set of \( \mu_i(t_i) \)-probability zero. But, outside this null set, we can set \( \sigma_{-i} \) equal to a measurable selection from the correspondence \( R_{-i}^{k-1}(\cdot, G, \varepsilon) \), thus ensuring that (3) is satisfied everywhere provided \( v(\Theta \times \text{graph} \ R_{-i}^{k-1}) = 1 \) (as opposed to almost everywhere). The fact that such a measurable selection exists follows from the upper hemi-continuity of \( R_{-i}^{k-1}(\cdot, G, \varepsilon) \) (in the product topology) and the Kuratowski-Nyl-Nardzewski Selection Theorem.
(iv) for every $1 \leq n \leq N$, $a_{j,n}^* \in R_j (t_{j,n}, G)$;

(v) for every $1 \leq n \leq N$ and $s_j \in T_j$ with $d_j^k (s_j, t_{j,n}) > \varepsilon$, $a_{j,n}^* \notin R_j (s_j, G, \frac{\varepsilon}{2})$;

Proof. The proof is by induction on $k$. Consider first $k = 1$ and $j = 1$ ($j = 2$ can be similarly proved). Fix a finite set of player 1’s types $\{t_{1,1}, t_{1,2}, \ldots, t_{1,N}\}$. Enumerate the nonempty subsets of $\Theta$ as $E_1, E_2, \ldots, E_L$. For each $(n, \ell) \in \{1, 2, \ldots, N\} \times \{0, 1, \ldots, L\}$ consider the function $\phi_{n,\ell} : \Theta \rightarrow [-1, 1]$ described in the following table:

<table>
<thead>
<tr>
<th>$\ell$</th>
<th>$\theta \in E_{\ell}$</th>
<th>$\theta \notin E_{\ell}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>$\ell \geq 1$</td>
<td>$-(1 - \mu_1 (E_{\ell}</td>
<td>t_{1,n})$</td>
</tr>
</tbody>
</table>

Thus, the functions $\phi_{n,\ell}$ define an auxiliary game between player 1 and Nature, where $\ell = 0$ is a safe bet for player 1, and $\ell \geq 1$ is a risky bet on the event $\theta \notin E_{\ell}$. The rewards of the risky bets are such that:

- any type that has the same first-order beliefs as type $t_{1,n}$ is exactly indifferent between $\ell = 0$ and any $\ell \geq 1$;
- any type whose first-order belief is different from that of $t_{1,n}$ strictly prefers some risky bet $\ell \geq 1$ than the safe bet $\ell = 0$.

We use the functions $\phi_{n,\ell}$ to construct a game $G = (A_i, g_i)_{i \in I}$ to prove our claim for $k = 1$. In this game,

$A_1 = (\{1, 2, \ldots, N\} \times \{0, 1, \ldots, L\}) \cup \{a_1^0, a_1^c\}$ and $A_2 = \{1, 2, \ldots, N\} \cup \{a_2^0, a_2^c\}$.

Player 1’s payoffs are specified as follows:

- $a_1^0$ is a zero action for player 1;
- if player 1 chooses $a_1^c$, she gets 3 if player 2 chooses $a_2^c$, and gets 0 otherwise (regardless of $\theta$);
- if player 1 chooses $(n, \ell) \in \{1, \ldots, N\} \times \{0, \ldots, L\}$ and the state is $\theta$, she gets $\phi_{n,\ell} (\theta)$ if player 2 chooses $n$, and she gets $\phi_{n,\ell} (\theta) - 1$ if player 2 chooses any action different from $n$.

Player 2’s payoffs are specified as follows:

- Player 2 gets 3 if $(a_1^c, a_2^c)$ is chosen (regardless of $\theta$), and gets 0 otherwise.
Thus, when the state is $\theta$, we can draw the payoff matrix $g(\cdot, \cdot, \theta)$ as follows:

<table>
<thead>

</table>

Since $\phi_{n,\ell}(\theta) \in [-1, 1]$ for all $n, \ell$ and $\theta$, game $G$ has payoffs bounded between $-2$ and $3$. We claim that $G$, along with the actions $a_{1,n}^* \triangleq (n, 0), n = 1, \ldots, N$, satisfy properties (i)–(v) for $k = 1$. Properties (i) and (ii) clearly hold. To prove (iii), first note that $R_2 (., G, \gamma) = R_2^1 (., G, \gamma) = A_2$ for all $\gamma \geq 0$. Indeed, the profile of correspondences $(\zeta_j)_{j \in I}$, where $\zeta_2 (t_2) = A_2$ and $\zeta_1 (t_1) = \{a_1^0, a_1^\gamma\}$ for all $t_1$ and $t_2$, has the $\gamma$-best reply property. It follows that $R_1 (., G, \gamma) = R_1^1 (., G, \gamma)$ for all $\gamma \geq 0$. Hence, (iii) holds.

It remains to prove (iv) and (v). First, $(n, 0)$ is rationalizable for $t_{1,n}$, since given the conjecture that player 2 plays $n$, type $t_{1,n}$ gets 0 by playing $(n, \ell)$ for any $\ell$:

$$
\mu_1 \left( E_{\ell} | t_{1,n} \right) \cdot \left( 1 - \mu_1 \left( E_{\ell} | t_{1,n} \right) \right) + \left( 1 - \mu_1 \left( E_{\ell} | t_{1,n} \right) \right) \cdot \mu_1 \left( E_{\ell} | t_{1,n} \right) = 0,
$$

and gets at most 0 by playing any action not in $\{(n, 0), \ldots, (n, L)\}$. Thus, (iv) holds for $a_{1,n}^* = (n, 0)$. Second, consider any type $s_1$ with $d_1^0 \left( s_1, t_{1,n} \right) > \varepsilon$. Then, there exists some $1 \leq \ell \leq L$ such that

$$
\mu_1 \left( E_{\ell} | t_{1,n} \right) > \mu_1 \left( E_{\ell}^{e,0} | s_1 \right) + \varepsilon = \mu_1 \left( E_{\ell} | s_1 \right) + \varepsilon.
$$

Then, given any conjecture about the behavior of player 2, the difference in expected payoffs between $(n, \ell)$ and $(n, 0)$ for type $s_1$ is

$$
\mu_1 \left( E_{\ell} | s_1 \right) \cdot \left( 1 - \mu_1 \left( E_{\ell} | t_{1,n} \right) \right) + \left( 1 - \mu_1 \left( E_{\ell} | s_1 \right) \right) \cdot \mu_1 \left( E_{\ell} | t_{1,n} \right)
\quad = \mu_1 \left( E_{\ell} | t_{1,n} \right) - \mu_1 \left( E_{\ell} | s_1 \right) > \varepsilon.
$$

Hence, $a_{1,n}^* = (n, 0)$ is not $\varepsilon$-rationalizable for type $s_1$, which proves (v).

We now prove our claim for $k + 1$ assuming that it holds for $k$. Again, we assume $j = 1$, and the proof for $j = 2$ is similar. Let $t_{1,1}, \ldots, t_{1,N}$ be arbitrary finite types of player 1. Consider the finite set $T_2 = \{t_{2,1}, t_{2,2}, \ldots, t_{2,N'}\}$ of all types of player 2 that are assigned positive probability by some $t_{1,n}$, for $n = 1, \ldots, N$. By the induction hypothesis, we can find a game $G = (A_i, g_i)_{i \in I}$, a set of actions $\{a_{1,1}^*, a_{1,2}^*, \ldots, a_{1,N'}^*\} \subset A_2$, and action profiles $a^0$ and $a^\gamma$ in $G$, that satisfy properties (i)–(v) relative to the finite set of finite types $T_2$.

Let $T_2^k = \{t_{2,1}^k, t_{2,2}^k, \ldots, t_{2,N'}^k\}$ be the set of $k$-order beliefs of types in $T_2$. Enumerate the nonempty subsets of $\Theta \times T_2^k$ as $E_1, E_2, \ldots, E_L$. For each $1 \leq \ell \leq L$, define

$$
F_\ell = \left\{ (a_{2,n}', \theta) : 1 \leq n' \leq N', (\theta, t_{2,n'}) \in E_\ell \right\}.
$$

The equality follows because $a^0 = 0$ and $\Theta$ is endowed with the discrete metric.
For each \((n, \ell) \in \{1, \ldots, N\} \times \{0, \ldots, L\}\), define a function \(\phi_{n,\ell} : A_2 \times \Theta \to [-1, 1]\) as in the following table:

<table>
<thead>
<tr>
<th>(\ell = 0)</th>
<th>(\ell \geq 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a_2, \theta \in F_\ell)</td>
<td>(1 )</td>
</tr>
<tr>
<td>(a_2, \theta \notin F_\ell)</td>
<td>((-1 - \mu_1(E_\ell</td>
</tr>
</tbody>
</table>

We use the game \(G\) and the functions \(\phi_{n,\ell}\) to define a new game \(\tilde{G} = (\tilde{A}_i, \tilde{g}_i)\) to prove our claim for \(k + 1\). In this game,

\[
\tilde{A}_1 = A_1 \cup \{1, \ldots, N\} \times \{0, 1, \ldots, L\} \cup \{\tilde{a}^0_1\} \text{ and } \tilde{A}_2 = A_2 \times \{0, 1, \ldots, N\}.
\]

Player 1’s payoffs are specified as follows (see also the following table):

- \(\tilde{a}^0_1\) is a zero action for player 1;
- if player 1 chooses \(a_1 \in A_1\) and the state is \(\theta\), he gets \(g_1(a_1, a_2, \theta)\) if player 2 chooses \((a_2, 0) \in A_2 \times \{0\}\), and gets \(g_1(a_1, a_2, \theta) - 3\) otherwise.
- if player 1 chooses \((n, \ell)\) and the state is \(\theta\), he gets \(\phi_{n,\ell}(a_2^\ell, \theta) - 1\) if player 2 chooses \((a_2, 0) \in A_2 \times \{0\}\); he gets \(\phi_{n,\ell}(a_2, \theta)\) if player 2 chooses \((a_2, n) \in A_2 \times \{n\}\); and he gets \(\phi_{n,\ell}(a_2^\ell, \theta) - 1\) if player 2 chooses \((a_2, m) \in A_2 \times \{m\}\) with \(m \neq n\) and \(m \neq 0\).

</tbody>
</table>

Player 2’s payoffs are specified as follows:

- If player 2 chooses \((a_2, m)\), he gets \(g_2(a_2, a_1, \theta)\) if player 1 chooses \(a_1 \in A_1\), and he gets \(g_2(a_2, a_1^\ell, \theta)\) otherwise.

\[\text{Recall that we identify any measurable subset } E \subseteq T^L_2 \text{ with the cylinder}
\{t_2 \in T_2 : \text{ the } k\text{-order belief of } t_2 \text{ belongs to } E\}.
\]

\[27\]
By the induction hypothesis, game $G$ satisfies property (ii) and has payoffs in the interval $[-5, 3]$; it follows that game $\tilde{G}$ also has payoffs in the interval $[-5, 3]$.

We now prove that game $\tilde{G}$, along with the actions $a_{1,n}^* \overset{\text{def}}{=} (n, 0)$, $n = 1, \ldots, N$, satisfy properties (i)–(v) for $k + 1$. First, (i) follows because $a_1^1$ and $(a_2^0, n)$ are zero actions for players 1 and 2, respectively. Second, (ii) is satisfied by the coordination pair $(a_1^c, (a_2^c, 0))$: for any $a_1 \in \tilde{A}_1$ and $\theta \in \Theta$,

$$\tilde{g}_1 (\tilde{a}_1, (a_2^c, 0) \; , \theta) \geq \min \left\{ g_1 (a_1, a_2^c, \theta) , \min_{n, \ell} I_{n, \ell} (a_2^c, \theta) / 2 - 1 , 0 \right\} \geq -2;$$

moreover, $\tilde{g}_2 ((a_2, n), a_1^c, \theta) = g_2 (a_2, a_1^c, \theta) \geq -2$ for any $(a_2, n) \in \tilde{A}_2$ and $\theta \in \Theta$, and $\tilde{g}_1 (a_1^c, (a_2^c, 0), \theta) = \tilde{g}_2 ((a_2^c, 0), a_1^c, \theta) = 3$ for any $\theta \in \Theta$.

The proof of (iii)–(v) relies on the following claim, whose proof is postponed.

**Claim 2.** For every integer $r \geq 0$ and $\gamma \in [0, 1/2]$,

1. $R_1^r (\cdot, \tilde{G}, \gamma) \cap A_1 = R_1^r (\cdot, G, \gamma)$;
2. $R_2^r (\cdot, \tilde{G}, \gamma) = R_2^r (\cdot, G, \gamma) \times \{0, 1, 2, \ldots, N\}$.

We now prove that Claim 2 implies properties (iii)–(v).

(iii): By the induction hypothesis, $R_2 (\cdot, G, \gamma) = R_2^k (\cdot, G, \gamma)$. Thus, Claim 2 implies that $R_2 (\cdot, \tilde{G}, \gamma) = R_2^k (\cdot, \tilde{G}, \gamma)$; this, in turn, implies $R_1 (\cdot, \tilde{G}, \gamma) = R_1^{k+1} (\cdot, \tilde{G}, \gamma)$ and hence (iii).

(iv): Given any $1 \leq n \leq N$, consider the conjecture $\sigma_2 : \Theta \times T_2 \rightarrow \Delta (\tilde{A}_2)$ such that $\sigma_2 (\theta, (a_{2,n'}, n)) = 1$ for each $n' = 1, \ldots, N'$ and $\theta \in \Theta$. By part 1 of Claim 2 and the fact that $G$ satisfies property (iv) (by the induction hypothesis), $\sigma_2$ is a rationalizable conjecture in $\tilde{G}$. Moreover, given such a conjecture, $t_{1,n}$ gets an expected payoff of 0 by playing $(n, \ell)$ for any $\ell$, and gets at most 0 by playing any action in $\tilde{A}_1 \setminus \{(n, 0), \ldots, (n, L)\}$:

$$\pi_{t_{1,n}, \sigma_2 (F_\ell)} \cdot \left( - (1 - \mu_1 (E_\ell | t_{1,n})) \right) + \left( 1 - \pi_{t_{1,n}, \sigma_2 (F_\ell)} \right) \cdot \mu_1 (E_\ell | t_{1,n})$$

$$= \mu_1 (E_\ell | t_{1,n}) \cdot \left( - (1 - \mu_1 (E_\ell | t_{1,n})) \right) + \left( 1 - \mu_1 (E_\ell | t_{1,n}) \right) \cdot \mu_1 (E_\ell | t_{1,n}) = 0.$$ 

In particular, $a_{1,n}^* = (n, 0)$ is a best reply for $t_{1,n}$.

(v): Fix $1 \leq n \leq N$ and consider any type $s_1$ with $d_1^{k+1} (s_1, t_{1,n}) > \varepsilon$. Then, there exists some $1 \leq \ell \leq L$ such that

$$\mu_1 (E_\ell | t_{1,n}) > \mu_1 \left( (E_\ell)^{s_1} | s_1 \right) + \varepsilon.$$ 

It follows that, given any $\xi$-rationalizable conjecture $\sigma_2 : \Theta \times T_2 \rightarrow \Delta (\tilde{A}_2)$, the difference in expected payoffs between actions $(n, \ell)$ and $(n, 0)$ for type $s_1$ is at least $\varepsilon / 2$. To prove this, we consider two cases separately: when player 2 chooses $m = n$; and when player 2 chooses $m \neq n$. 

28
First, conditional on player 2 choosing $n$, the expected payoff difference between actions $(n, \ell)$ and $(n, 0)$ for type $s_1$, given an arbitrary $\frac{\epsilon}{2}$-rationalizable conjecture $\sigma_2$, is

$$
\sum_{a_2, \theta} \phi_{n, \ell}(a_2, \theta) \pi_{s_1, \sigma_2}(a_2, \theta | n) = \pi_{s_1, \sigma_2}(F_\ell | n) \cdot \left( - (1 - \mu_1 (E_\ell | t_1, n)) \right) + (1 - \pi_{s_1, \sigma_2}(F_\ell | n)) \cdot \mu_1 (E_\ell | t_1, n).
$$

But, for any $(\theta, s_2) \in \Theta \times T_2$ and $n' = 1, \ldots, N'$,

$$
\sigma_2(\theta, s_2)[a^*_2, n', n] > 0 \implies (a^*_2, n') \in R_2 \left( s_2, \tilde{G}, \frac{\epsilon}{2} \right) \quad \text{(since } \sigma_2 \text{ is } \frac{\epsilon}{2} \text{-rationalizable)}
$$

$$
\implies a^*_2, n' \in R_2 \left( s_2, G, \frac{\epsilon}{2} \right) \quad \text{(by Claim 2)}
$$

$$
\implies \pi_{s_1, \sigma_2}(F_\ell | n') \leq \mu_1 \left( \left( E_\ell \right)^{\epsilon, k} | s_1 \right),
$$

and thus, if $\pi_{s_1, \sigma_2}(n) > 0$,

$$
\pi_{s_1, \sigma_2}(F_\ell | n) \leq \mu_1 \left( \left( E_\ell \right)^{\epsilon, k} | s_1 \right),
$$

which implies

$$
\sum_{a_2, \theta} \phi_{n, \ell}(a_2, \theta) \pi_{s_1, \sigma_2}(a_2, \theta | n)
\geq \mu_1 \left( \left( E_\ell \right)^{\epsilon, k} | s_1 \right) \cdot \left( - (1 - \mu_1 (E_\ell | t_1, n)) \right) + (1 - \mu_1 \left( \left( E_\ell \right)^{\epsilon, k} | s_1 \right)) \cdot \mu_1 (E_\ell | t_1, n)
\geq \mu_1 (E_\ell | t_1, n) - \mu_1 \left( \left( E_\ell \right)^{\epsilon, k} | s_1 \right) > \epsilon.
$$

Second, conditional on player 2 choosing $m \neq n$, the expected payoff difference between actions $(n, \ell)$ and $(n, 0)$ for type $s_1$ (given any conjecture) is at least $\frac{\epsilon}{2} - \frac{\epsilon}{2} = \mu_1 (E_\ell | t_1, n) / 2 > \epsilon / 2$. (This is because $a^*_2 = a^*_2, n'$ for all $n'$, and hence $(a^*_2, \theta) \notin F_\ell$ for every $\theta$.) We have thus shown that, given any $\epsilon / 2$-rationalizable conjecture, and conditional on any choice of $m = 0, \ldots, N$ by player 2 with $\pi_{s_1, \sigma_2}(m) > 0$, type $s_1$ gains at least $\epsilon / 2$ by deviating from $(n, 0)$ to $(n, \ell)$. Thus, he also gains $\epsilon / 2$ unconditionally on $m$, and hence property (v) follows.

To conclude the proof, it remains to prove Claim 2. We prove it by induction on $r \geq 0$. First, the claim is trivially true for $r = 0$. We now consider $r \geq 1$, assume that the claim holds for any $0 \leq r' < r$, and prove that it also holds for $r$.

$$
R_1^r (t_1, G, \gamma) \supset R_1^r (t_1, \tilde{G}, \gamma) \cap A_1:
$$

Let $a_1 \in R_1^r (t_1, \tilde{G}, \gamma) \cap A_1$. Then, there is an $(r - 1)$-order $\gamma$-rationalizable conjecture $\tilde{\sigma}_2 : \Theta \times T_2 \rightarrow \Delta (\tilde{A}_2)$ in $\tilde{G}$ such that for any $a_1' \in A_1$,

$$
\sum_{(a_2, n) \in \tilde{A}_2} \left[ \tilde{g}_1(a_1, (a_2, n), \theta) - \tilde{g}_1(a_1', (a_2, n), \theta) \right] \tilde{\sigma}_2 (\theta, t_2)[(a_2, n)] \geq -\gamma.
$$

(5)
Consider the mapping \( \varphi_2 : \tilde{A}_2 \to A_2 \),
\[
\varphi_2 (a_2, n) = \begin{cases} 
a_2, & \text{if } n = 0; 
\tilde{a}_2^n, & \text{if } n \neq 0.
\end{cases}
\]

Define \( \sigma_2 \) as the conjecture in \( G \) such that \( \sigma_2 (\theta, t_2) [a_2] \overset{\text{def}}{=} \tilde{\sigma}_2 (\theta, t_2) [\varphi_2^{-1} (a_2)] \) for any \((\theta, t_2) \in \Theta \times T_2 \) and \( a_2 \in A_2 \). Since \( \tilde{\sigma}_2 \) is \((r - 1)\)-order \( \gamma \)-rationalizable in \( \tilde{G} \), \( \tilde{\sigma}_2 (\theta, t_2) [(a_2, 0)] > 0 \) implies \((a_2, 0) \in R^{r-1}_2 (t_2, \tilde{G}, \gamma) \), and by the induction hypothesis, \( a_2 \in R^{r-1}_2 (t_2, G, \gamma) \). Moreover, \( a_2^\xi \) is part of a coordination pair in \( G \), hence \( a_2^\xi \) is rationalizable in \( G \) for any type. Thus, \( \sigma_2 \) is an \((r - 1)\)-order \( \gamma \)-rationalizable conjecture in \( G \). Moreover, for any \( a'_1 \in A_1 \),
\[
\int_{\Theta \times T_2} d\mu_1 (\theta, t_2 | t_1) \sum_{(a_2, n) \in A_2} [\tilde{g}_1 (a_1, (a_2, n), \theta) - g_1 (a'_1, (a_2, n), \theta)] \tilde{\sigma}_2 (\theta, t_2) [(a_2, n)]
\]
\[
= \int_{\Theta \times T_2} d\mu_1 (\theta, t_2 | t_1) \left( \sum_{a_2 \in A_2} [g_1 (a_1, a_2, \theta) - g_1 (a'_1, a_2, \theta)] \tilde{\sigma}_2 (\theta, t_2) [(a_2, 0)]
\right)
\]
\[
+ \left[ (g_1 (a_1, a_2^\xi, \theta) - 3) - (g_1 (a'_1, a_2^\xi, \theta) - 3) \right] \tilde{\sigma}_2 (\theta, t_2) [(a_2, n) \in \tilde{A}_2 : n > 0] \right)
\]
\[
= \int_{\Theta \times T_2} d\mu_1 (\theta, t_2 | t_1) \sum_{a_2 \in A_2} [g_1 (a_1, a_2, \theta) - g_1 (a'_1, a_2, \theta)] \sigma_2 (\theta, t_2) [a_2] \tag{6}
\]

Then, (5) and (6) imply \( a_1 \in R^T_1 (t_1, G, \gamma) \).

\[
R^T_1 (t_1, G, \gamma) \subset R^T_1 (t_1, \tilde{G}, \gamma) \cap A_1: \quad \text{Let } a_1 \in R^T_1 (t_1, G, \gamma). \text{ Then, there exists an } (r - 1)\text{-order } \gamma \text{-rationalizable conjecture } \sigma_2 : \Theta \times T_2 \to \Delta (A_2) \text{ in } G \text{ such that for any } a'_1 \in A_1,
\]
\[
\int_{\Theta \times T_2} d\mu_1 (\theta, t_2 | t_1) \sum_{a_2 \in A_2} [g_1 (a_1, a_2, \theta) - g_1 (a'_1, a_2, \theta)] \sigma_2 (\theta, t_2) [a_2] \geq -\gamma. \tag{7}
\]

Define \( \tilde{\sigma}_2 \) as the conjecture in \( \tilde{G} \) such that \( \tilde{\sigma}_2 (\theta, t_2) [(a_2, 0)] \overset{\text{def}}{=} \sigma_2 (\theta, t_2) [a_2] \) for any \((\theta, t_2) \in \Theta \times T_2 \) and \( a_2 \in A_2 \) (and thus \( \tilde{\sigma}_2 (\theta, t_2) [(a_2, n)] = 0 \) for any \( n > 0 \)). Since \( \sigma_2 \) is \((r - 1)\)-order \( \gamma \)-rationalizable in \( G \), \( \sigma_2 (\theta, t_2) [a_2] > 0 \) implies \( a_2 \in R^{r-1}_2 (t_2, G, \gamma) \), and by the induction hypothesis, \((a_2, 0) \in R^{r-1}_2 (t_2, \tilde{G}, \gamma) \). Hence, \( \tilde{\sigma}_2 \) is \((r - 1)\)-order \( \gamma \)-rationalizable in \( G \). We will now show that \( a_1 \) is a \( \gamma \)-best reply to \( \tilde{\sigma}_2 \) for \( t_1 \) in \( \tilde{G} \). First, by (7) and the definition of \( \tilde{\sigma}_2 \),
\[
\int_{\Theta \times T_2} d\mu_1 (\theta, t_2 | t_1) \sum_{a_2 \in A_2} [g_1 (a_1, a_2, \theta) - g_1 (a'_1, a_2, \theta)] \tilde{\sigma}_2 (\theta, t_2) [(a_2, 0)] \geq -\gamma \quad \forall a'_1 \in A_1.
\tag{8}
\]

Second, setting \( a'_1 = a_1^0 \) in (7) and recalling that \( \gamma < 1/2 \),
\[
\int_{\Theta \times T_2} d\mu_1 (\theta, t_2 | t_1) \sum_{a_2 \in A_2} g_1 (a_1, a_2, \theta) \sigma_2 (\theta, t_2) [a_2] \geq -\gamma > -1/2.
\]
Since $\phi_{n,\ell} (a_2^r, \theta) / 2 - 1 \leq -1/2$ for any $n$ and $\ell$,
\[
\int_{\Theta \times T_1} d\mu_1(\theta, t_1 | t_2) \sum_{a_2 \in A_2} [\tilde{g}_1 (a_1, a_2, \theta) - \tilde{g}_1 ((n, \ell), a_2, \theta)] \bar{\sigma}_2 (\theta, t_2) [(a_2, 0)] \geq 0 \quad \forall n, \ell.
\]
(9)

By (8) and (9), $a_1$ is a $y$-best reply to $\bar{\sigma}_2$ for $t_1$ in $\hat{G}$, and hence $a_1 \in R_1^r (t_1, \hat{G}, y)$.

$R_2^r (t_2, \hat{G}, y) \subset R_2^r (t_2, G, y) \times \{0, 1, \ldots, N\}$: Suppose $(a_2, m) \in R_2^r (t_2, \hat{G}, y)$. Then, there is an $(r - 1)$-order $y$-rationalizable conjecture $\bar{\sigma}_1 : \Theta \times T_1 \rightarrow \Delta (\hat{A}_1)$ in $\hat{G}$ such that for any $(a_2', m') \in \hat{A}_2$,
\[
\int_{\Theta \times T_1} d\mu_2(\theta, t_1 | t_2) \sum_{\hat{a}_1 \in \hat{A}_1} [\tilde{g}_2 ((a_2, m), \hat{a}_1, \theta) - \tilde{g}_2 ((a_2', m'), \hat{a}_1, \theta)] \bar{\sigma}_1 (\theta, t_1) [\hat{a}_1] \geq -y.
\]

Consider the map $\varphi_1 : \hat{A}_1 \rightarrow A_1$,
\[
\varphi_1 (\hat{a}_1) = \begin{cases} 
\hat{a}_1, & \text{if } \hat{a}_1 \in A_1; \\
\hat{a}_1^c, & \text{if } \hat{a}_1 \notin A_1.
\end{cases}
\]

Let $\sigma_1$ be the conjecture in $G$ such that $\sigma_1 (\theta, t_1) [a_1] \equiv \bar{\sigma}_1 (\theta, t_1) [\varphi_1^{-1} (a_1)]$ for any $(\theta, t_1) \in \Theta \times T_1$ and $a_1 \in A_1$. Since $\bar{\sigma}_1$ is $(r - 1)$-order $y$-rationalizable in $\hat{G}$, for any $\hat{a}_1 \in A_1$, $\bar{\sigma}_1 (\theta, t_1) [\hat{a}_1] > 0$ implies $\hat{a}_1 \in R_1^r (t_1, \hat{G}, y)$, and by the induction hypothesis, $\hat{a}_1 \in R_1^r (t_1, G, y)$. Moreover, $\hat{a}_1^c$ is part of a coordination pair in $G$, hence it is rationalizable for any type. Thus, $\sigma_1$ is an $(r - 1)$-order $y$-rationalizable conjecture in $G$. Moreover, (5) implies that for any $a_2' \in A_2$,
\[
-\gamma \leq \int_{\Theta \times T_1} d\mu_2(\theta, t_1 | t_2) \sum_{\hat{a}_1 \in \hat{A}_1} [\tilde{g}_2 ((a_2, m), \hat{a}_1, \theta) - \tilde{g}_2 ((a_2', m'), \hat{a}_1, \theta)] \bar{\sigma}_1 (\theta, t_1) [\hat{a}_1]
\]
\[
= \int_{\Theta \times T_1} d\mu_2(\theta, t_1 | t_2) \left( \sum_{a_1 \in A_1} [g_2 (a_2, a_1, \theta) - g_2 (a_2', a_1, \theta)] \bar{\sigma}_1 (\theta, t_1) [a_1] 
\right.
\]
\[
+ [g_2 (a_2, a_1^c, \theta) - g_2 (a_2', a_1^c, \theta)] \bar{\sigma}_1 (\theta, t_1) [\hat{A}_1 \setminus A_1] \right)
\]
\[
= \int_{\Theta \times T_1} d\mu_2(\theta, t_1 | t_2) \sum_{a_1 \in A_1} [g_2 (a_2, a_1, \theta) - g_2 (a_2', a_1, \theta)] \sigma_1 (\theta, t_1) [a_1]
\]

Therefore, $a_2 \in R_2^y (t_2, G, y)$.

$R_2^y (t_2, G, y) \supset R_2^y (t_2, G, y) \times \{0, 1, \ldots, N\}$: Let $(a_2, m) \in R_2^y (t_2, G, y) \times \{0, 1, \ldots, N\}$. Then, there is an $(r - 1)$-order $y$-rationalizable conjecture $\sigma_1 : \Theta \times T_1 \rightarrow \Delta (A_1)$ in $G$ such that for any $a_2' \in A_2$,
\[
\int_{\Theta \times T_1} d\mu_2(\theta, t_1 | t_2) \sum_{a_1 \in A_1} [g_2 (a_2, a_1, \theta) - g_2 (a_2', a_1, \theta)] \sigma_1 (\theta, t_1) [a_1] \geq -\gamma.
\]
(10)
Let $\bar{\sigma}_1$ be the conjecture in $\bar{G}$ such that $\bar{\sigma}_1(\theta, t_1) [a_1] \overset{\text{def}}{=} \sigma_1(\theta, t_1) [a_1]$ for any $(\theta, t_1) \in \Theta \times T_1$ and $a_1 \in A_1$ (and thus $\bar{\sigma}_1(\theta, t_1) [a_1] = 0$ for any $a_1 \notin A_1$). Since $\sigma_1$ is $(r-1)$-order $\gamma$-rationalizable in $G$, $\sigma_1(\theta, t_1) [a_1] > 0$ implies $a_1 \in R_{t_1}^{r-1}(t_1, G, \gamma)$, and by the induction hypothesis, $a_1 \in R_{t_1}^{r-1}(t_1, \bar{G}, \gamma)$. Hence, $\bar{\sigma}_1$ is $(r-1)$-order $\gamma$-rationalizable in $\bar{G}$. Since $\bar{g}_2((a_2, m), a_1, \theta) = \bar{g}_2((a_2, m'), a_1, \theta)$ for any $m$ and $m'$, it follows from (10) that $(a_2, m) \in R_2^{1}(t_2, \bar{G}, \gamma)$.

**Corollary 1.** For every $\varepsilon > 0$, player $i$, positive integer $k$ and finite type $t_i \in T_i$, there exists a game $G$ with $|G| \leq M$, and an action $a_i$ of player $i$ in $G$, such that:

(i) $R_j(\cdot, G, \gamma) = R_j^k(\cdot, G, \gamma)$ for every $\gamma \in [0, M/10]$ and $j \in I$;

(ii) $a_i \in R_i(t_i, G)$;

(iii) $a_i \notin R_i^k(s_i, G, M\varepsilon/10)$ for every $s_i \in T_i$ with $d_i^k(s_i, t_i) > \varepsilon$.

**Proof.** Immediate implication of Lemma 3, upon rescaling the payoffs by a factor of $M/5$. ■

**Lemma 4.** For every $\varepsilon > 0$ there exists $\delta > 0$ such that for every $i \in I$ and $s_i, t_i \in T_i$ with $d_i^{\text{low}}(s_i, t_i) > \varepsilon$ there is a game $G$ with $|G| \leq M$ such that $R_i(t_i, G) \notin R_i(s_i, G, \delta)$.

**Proof.** Fix an $\varepsilon > 0$, a player $i$, an integer $k \geq 1$ and types $s_i, t_i \in T_i$ with $d_i^k(s_i, t_i) > \varepsilon$. Fix $0 < \delta < M\varepsilon/10$ and choose $\rho > 0$ small enough that

$$\frac{M(\varepsilon - \rho)}{10} - 4M\rho > \delta. \quad (11)$$

Since finite types are dense in the product topology, there is a finite type $t_i'$ such that $d_i^k(t_i', t_i) < \rho$. Then, $d_i^k(s_i, t_i') > \varepsilon - \rho$. By Corollary 1, there is some game $G' = (A_i', g_i')_{i \in I}$ with $|G'| \leq M$, and some action $a_i'$ of player $i$ in $G'$, such that $a_i' \in R_i(t_i', G', 0)$ and $a_i' \notin R_i^k(s_i, G', M(\varepsilon - \rho)/10)$.

By Proposition 2 in Chen, Di Tillio, Faingold, and Xiong (2010), $a_i' \in R_i^k(t_i, G', 4M\rho)$. Then, it follows from (i) of Corollary 1 that $a_i' \in R_i(t_i, G', 4M\rho)$ and $a_i' \notin R_i(s_i, G', M(\varepsilon - \rho)/10)$.

To conclude, consider the game $G = (A_j, g_j)_{j \in I}$, defined as follows:

$$A_i = A_i', \quad A_{-i} = A_{-i} \times A_i',$$

$$g_i(a_i, (a_{-i}^{-i}, a_{-i}^i), \theta) = \begin{cases} 
g_i'(a_i, a_{-i}^{-i}, \theta) + 4M\rho : a_i' = a_i^i \\
g_i'(a_i, a_{-i}^{-i}, \theta) : \text{otherwise}, \end{cases}$$

and

$$g_{-i}((a_{-i}^{-i}, a_{-i}^i), a_i, \theta) = g_{-i}'(a_{-i}^{-i}, a_i, \theta).$$

In game $G$, player $-i$ is indifferent among all actions $a_{-i}^{-i}$; moreover, player $i$ gets an additional payoff of $4M\rho$ whenever his action matches player $-i$’s choice of $a_{-i}^i$. Therefore, $R_i(\cdot, G', \gamma + 4M\rho)$ for every $\gamma \geq 0$. In particular, we have that $a_i' \in R_i(t_i, G, 0)$ and $a_i' \notin R_i(s_i, G, \delta)$, where the inclusion follows from (11).34 ■

34If necessary, rescale the payoffs from $G$ to ensure $|G| \leq M$, and rescale $\delta$ by the same factor.
The only if direction of Theorem 1 then follows directly from Lemma 4.

A.3 Proof of Theorem 2

We begin with the following auxiliary result about the structure of ICR.

Lemma 5. Fix a game $G = (A_i, g_i)_{i \in I}$ and $\varepsilon \geq 0$. For every integer $k \geq 1$, $i \in I$ and $t_i \in T_i$, we have $a_i \in R^k_i (t_i, G, \varepsilon)$ if and only if, for every $\alpha_i \in \Delta (A_i)$,

$$\sum_{\theta \in \Theta, B \subseteq A_{-i}} \max_{a_{-i} \in B} \left[ g_i (a_i, a_{-i}, \theta) - g_i (\alpha_i, a_{-i}, \theta) \right] \times \mu_i \left( \theta \times \left\{ t_{-i} : R^{k-1}_{-i} (t_{-i}, G, \varepsilon) = B \right\} \big| t_i \right) \geq -\varepsilon. \quad (12)$$

Likewise, $a_i \in R_i (t_i, G, \varepsilon)$ if and only if, for every $\alpha_i \in \Delta (A_i)$,

$$\sum_{\theta \in \Theta, B \subseteq A_{-i}} \max_{a_{-i} \in B} \left[ g_i (a_i, a_{-i}, \theta) - g_i (\alpha_i, a_{-i}, \theta) \right] \times \mu_i \left( \theta \times \left\{ t_{-i} : R_{-i} (t_{-i}, G, \varepsilon) = B \right\} \big| t_i \right) \geq -\varepsilon. \quad (13)$$

Proof. Straightforward implication of the characterization of ICR in terms of iterated dominance (see Appendix A.1). $\blacksquare$

The if direction of the theorem is an immediate consequence of the following lemma:

Lemma 6. Fix $\delta > 0$ and a game $G = (A_i, g_i)_{i \in I}$ and let $\mathcal{P}$ denote the strategic frame associated with $G$. For every integer $k \geq 0$, $i \in I$ and $s_i, t_i \in T_i$,

$$d^{k}_{i, \mathcal{P}} (s_i, t_i) < \delta \implies R_i (t_i, G) \subseteq R^k_i (s_i, G, 4M \delta).$$

In particular, for every $i \in I$ and $s_i, t_i \in T_i$,

$$d^{\infty}_{i, \mathcal{P}} (s_i, t_i) < \delta \implies R_i (t_i, G) \subseteq R_i (s_i, G, 4M \delta).$$

Proof. We need only prove the first result, as the second result is a straightforward implication of the first one. For $k = 0$ the result is trivially true, as $R^0_i \equiv A_i$. Proceeding by induction, we assume the result is true for $k \geq 0$ and show that it remains true for $k + 1$. Consider a pair of types $s_i, t_i$ with $d^{k+1}_{i, \mathcal{P}} (s_i, t_i) < \delta$. Fix an arbitrary $a_i \in R_i (t_i, G)$ and let us show that $a_i \in R^k_i (s_i, G, 4M \delta)$. Given $\alpha_i \in \Delta (A_i)$, by Lemma 5 we have

$$\sum_{\theta \in \Theta, B \subseteq A_{-i}} \Delta g_i (\theta, B) \mu_i \left( \theta \times [B] \big| t_i \right) \geq 0. \quad (14)$$
where, for each \( \theta \in \Theta \) and nonempty \( B \subseteq A_{-i} \),

\[
[B] \overset{\text{def}}{=} \left\{ t_{-i} : R_{-i}(t_{-i}, G) = B \right\},
\]

\[
\Delta g_i(\theta, B) \overset{\text{def}}{=} \max_{a_{-i} \in B} \left[ g_i(a_{-i}, a_{-i}, \theta) - g_i(\alpha_{i}, a_{-i}, \theta) \right].
\]

By Lemma 5, in order to prove that \( a_i \in R_{i}^{k+1}(s_i, G, 4M) \) we need only show that

\[
\sum_{\theta \in \Theta, B \subseteq A_{-i}} \Delta g_i(\theta, B) \mu_i(\theta \times [[B]] \wedge s_i) \geq -4M.
\]

where

\[
[[B]] \overset{\text{def}}{=} \left\{ t_{-i} : R_{-i}^k(t_{-i}, G, 4M) = B \right\}, \quad \forall B \subseteq A_{-i}.
\]

To prove this, first note that the induction hypothesis implies

\[
[B]_{\delta, k}^{\delta, k} \subseteq \bigcup_{C \supseteq B} [[C]], \quad \forall B \subseteq A_{-i}. \tag{15}
\]

Second, enumerate the elements of the finite set \( \Theta \times \{ B : \emptyset \neq B \subseteq A_{-i} \} \) as \( \{(\theta_n, B_n)\}_{n=1}^N \) (\( N = \#\Theta(2^{#A_{-i}} - 1) \)) so that

\[
\Delta g_i(\theta_n, B_n) \geq \Delta g_i(\theta_{n+1}, B_{n+1}) \quad \forall n = 1, \ldots, N - 1 \tag{16}
\]

and

\[
(\theta_m = \theta_n \text{ and } B_m \supseteq B_n) \implies m \leq n. \tag{17}
\]

\[\text{\textsuperscript{35}}\text{Such enumeration is possible because } \Delta g_i(\theta, B') \geq \Delta g_i(\theta, B) \text{ whenever } B' \supseteq B.\]
Then,

\[
\sum_{\theta \in \Theta, B \subseteq A_i} \Delta g_i(\theta, B) \mu_i(\theta \times \lbrack \lbrack B \rbrack \rbrack | s_i)
\]

\[

\geq \sum_{n=1}^{N} \Delta g_i(\theta_n, B_n) \left( \mu_i(\theta_n \times \lbrack \lbrack B_n \rbrack \rbrack | s_i) - \mu_i(\theta_n \times \lbrack B_n \rbrack | t_i) \right)
\]

\[

= N-1 \sum_{n=1}^{n} \left( \Delta g_i(\theta_n, B_n) - \Delta g_i(\theta_{n+1}, B_{n+1}) \right)
\]

\[

\times \left( \mu_i \left( \bigcup_{m=1}^{n} \theta_m \times \lbrack \lbrack B_m \rbrack \rbrack \bigg| s_i \right) - \mu_i \left( \bigcup_{m=1}^{n} \theta_m \times \lbrack B_m \rbrack \bigg| t_i \right) \right)
\]

\[

= \sum_{n=1}^{N-1} \left( \Delta g_i(\theta_n, B_n) - \Delta g_i(\theta_{n+1}, B_{n+1}) \right)
\]

\[

\times \left( \mu_i \left( \bigcup_{m=1}^{n} \theta_m \times \lbrack B_m \rbrack \bigg| s_i \right) - \mu_i \left( \bigcup_{m=1}^{n} \theta_m \times \lbrack B_m \rbrack \bigg| t_i \right) \right)
\]

\[

\geq N-1 \sum_{n=1}^{N-1} \left( \Delta g_i(\theta_n, B_n) - \Delta g_i(\theta_{n+1}, B_{n+1}) \right)
\]

\[

\times \left( \mu_i \left( \bigcup_{m=1}^{n} \theta_m \times \lbrack B_m \rbrack \bigg| s_i \right) - \mu_i \left( \bigcup_{m=1}^{n} \theta_m \times \lbrack B_m \rbrack \bigg| t_i \right) \right)
\]

\[

\geq N-1 \sum_{n=1}^{N-1} \left( \Delta g_i(\theta_n, B_n) - \Delta g_i(\theta_{n+1}, B_{n+1}) \right)(-\delta)
\]

\[

= -(\Delta g_i(\theta_1, B_1) - \Delta g_i(\theta_N, B_N))\delta
\]

\[

\geq -4M\delta,
\]

where (18) follows from (14); (19) follows by a standard “integration by parts” argument; (20) follows from the fact that \{\(\{\theta_m, \lbrack B_m \rbrack \}\} \}_{m=1}^{N} and \{\{\theta_m, \lbrack B_m \rbrack \}\} \}_{m=1}^{N} are partitions of \(\Theta \times \mathcal{F}_i\); (21) follows from (15), (16) and (17); (22) follows from the assumption that \(d_{i, P}^{k+1}(s_i, t_i) \leq \delta\), the fact that \([B_m] \in \mathcal{P}_i\) and (16); and (23) follows from \(|\Delta g_i| \leq 2M\). \( \blacksquare \)

Before turning to the proof of the only if direction of Theorem 2, we introduce some notation. First, given a frame \( \mathcal{P} \) and a type \( t_i \), let \( \mu_i(t_i) \rvert_{\Theta \times \mathcal{P}_i} \) denote the belief of type \( t_i \) over the events in \( \Theta \times \mathcal{P}_i \). We thus view \( \mu_i(t_i) \rvert_{\Theta \times \mathcal{P}_i} \) as an element of the finite-dimensional simplex \( \Delta(\Theta \times \mathcal{P}_i) \) (viewed as a subset of the Euclidean space \( \mathbb{R}^{\#\Theta \#\mathcal{P}_i} \)). Second, let \( \phi_i : \Delta(\Theta \times \mathcal{P}_i) \rightarrow \mathcal{P}_i \) designate the function that maps each \( q \in \Delta(\Theta \times \mathcal{P}_i) \) into \( \mathcal{P}_i(t_i) \), where \( t_i \) is some type with \( \mu_i(t_i) \rvert_{\Theta \times \mathcal{P}_i} = q \). Since \( \mathcal{P} \) is a frame, the definition of \( \phi_i \) is independent of the choice of \( t_i \). Third, given a game \( G = (A_i, g_i)_{i \in I} \), for each \( \pi_i \in \Delta(A_i \times \Theta) \) define a probability distribution
\( \pi_i^p \in \Delta(\Theta \times P_i) \) as follows:

\[
\pi_i^p(\theta, E) \overset{\text{def}}{=} \sum_{a_i \in \varphi_i^{-1}(E)} \pi_i(a_i, \theta) \quad \forall (\theta, E) \in \Theta \times P_i.
\]

The proof of the only if direction of Theorem 2 relies on Lemmas 7 and 8 and Corollary 2 below.

**Lemma 7.** Fix a frame \( \mathcal{P} \). For each \( \zeta > 0 \) there exist \( \epsilon > 0 \) and a game \( G = (A_i, g_i)_{i \in I} \) such that for each \( i \in I \),

(i) \( A_i \) is a finite subset of \( \Delta(\Theta \times P_{-i}) \) that is \( \sqrt{\epsilon} \)-dense (relative to the Euclidean norm \( \| \cdot \| \)) in every element of the partition \( \{ \varphi_i^{-1}(E) : E \in P_i \} \);

(ii) for each \( a_{-i}, a'_{-i} \in A_{-i} \),

\[
\varphi_{-i}(a_{-i}) = \varphi_{-i}(a'_{-i}) \implies g_i(a_{-i}, a_{-i}, \theta) = g_i(a_{-i}, a'_{-i}, \theta) \quad \forall \theta \in \Theta, a_{-i} \in A_i;
\]

(iii) for each \( \pi_{-i} \in \Delta(A_{-i} \times \Theta) \),

\[
BR_i(\pi_{-i}, G, \epsilon) \supseteq \{ a_i \in A_i : \| a_i - \pi_{-i} \|^p < \sqrt{\epsilon} \};
\]

(iv) for each \( \pi_{-i}, \pi'_{-i} \in \Delta(A_{-i} \times \Theta) \) with \( \| \pi_{-i}^p - \pi'_{-i} \|^p \geq \zeta \),

\[
BR_i(\pi'_{-i}, G, 2\epsilon) \cap \{ a_i \in A_i : \| a_i - \pi_{-i} \|^p < \sqrt{\epsilon} \} = \emptyset.
\]

**Proof.** Fix \( \zeta > 0 \) and a frame \( \mathcal{P} \). Let \( 0 < \epsilon < \zeta^2/(1 + \sqrt{3})^2 \). Cover the finite-dimensional simplex \( \Delta(\Theta \times P_{-i}) \) by a finite union of open balls \( B_1, \ldots, B_N \) of diameter \( \sqrt{\epsilon} \). Select one point from \( B_n \cap \varphi_i^{-1}(E) \), for each \( n = 1, \ldots, N \) and \( E \in P_i \), and let \( A_i \) denote the set of selected points. By construction, \( A_i \) satisfies (i).

Consider the quadratic score \( s_i : \Delta(\Theta \times P_{-i}) \times \Theta \times P_{-i} \rightarrow \mathbb{R} \),

\[
s_i(q, \theta, E) = 2q(\theta, E) - \| q \|^2 \quad \forall (q, \theta, E) \in \Delta(\Theta \times P_{-i}) \times \Theta \times P_{-i},
\]

which can be readily shown to satisfy

\[
s_i(q, q) - s_i(q', q) = \| q' - q \|^2 \quad q, q' \in \Delta(\Theta \times P_{-i}). \tag{24}
\]

Then, define \( g_i : A_i \times A_{-i} \times \Theta \rightarrow \mathbb{R} \),

\[
g_i(a_i, a_{-i}, \theta) = s_i(a_i, \theta, \varphi_{-i}(a_{-i})) \quad \forall (a_i, a_{-i}, \theta) \in A_i \times A_{-i} \times \Theta,
\]

which clearly satisfies (ii).
Given \( \pi_{-i} \in \Delta(A_{-i} \times \Theta) \) and \( a_i \in A_i \) with \( \|a_i - \pi_i^g\| < \sqrt{\varepsilon} \), for any \( a'_i \in A_i \) we have

\[
g_i(a_i, \pi_{-i}) - g_i(a'_i, \pi_{-i}) = s_i(a_i, \pi_i^g) - s_i(a'_i, \pi_i^g) = s_i(a_i, \pi_i^g) - s_i(\pi_i^g, \pi_{-i}) + s_i(\pi_i^g, \pi_{-i}) - s_i(a'_i, \pi_i^p) = -\|a_i - \pi_i^g\|^2 + \|a'_i - \pi_i^g\|^2 (\text{by } (24)) > -\varepsilon, (\text{by } \|a_i - \pi_i^g\| < \sqrt{\varepsilon})
\]

hence \( a_i \in BR_i(\pi_{-i}, G, \varepsilon) \), and this proves (iii).

Turning to (iv), let \( \pi_{-i}, \pi'_{-i} \in \Delta(A_{-i} \times \Theta) \) with \( \|\pi_i^g - \pi_i^g\| > \zeta \) and \( a_i \in A_i \) with \( \|a_i - \pi_i^g\| < \sqrt{\varepsilon} \). Then, \( \|a_i - \pi_i^g\| > \sqrt{\varepsilon} > \sqrt{3\varepsilon} \). By (i) we can find some \( a'_i \in A_i \) with \( \|a'_i - \pi_i^g\| < \sqrt{3\varepsilon} \). Thus,

\[
g_i(a_i, \pi'_{-i}) - g_i(a'_i, \pi'_{-i}) = s_i(a_i, \pi_i^g) - s_i(a'_i, \pi_i^p) = s_i(a_i, \pi_i^g) - s_i(\pi_i^g, \pi_{-i}) + s_i(\pi_i^g, \pi_{-i}) - s_i(a'_i, \pi_i^g) = -\|a_i - \pi_i^g\|^2 + \|a'_i - \pi_i^g\|^2 (\text{by } (24)) < -3\varepsilon + \varepsilon = -2\varepsilon,
\]

(by \( \|a_i - \pi_i^g\| > \sqrt{3\varepsilon} \) and \( \|a'_i - \pi_i^g\| < \sqrt{\varepsilon} \)) and hence \( a_i \notin BR_i(\pi'_{-i}, G, 2\varepsilon) \), as required.

Lemma 8. Fix \( \delta > 0 \) and a frame \( \mathcal{P} \). Let \( \varepsilon > 0 \) and \( G = (A_i, g_i)_{i \in I} \) satisfy the properties (i)-(iv) of Lemma 7 relative to \( \zeta = \delta/\#\Theta \cdot \max_i \#\mathcal{P}_i \). Then the following statements hold:

(a) for every \( i \in I \) and \( t_i \in T_i \),

\[
R(t_i, G, \varepsilon) \supseteq \left\{ a_i \in A_i \cap \varphi_i^{-1}(\mathcal{P}_i(t_i)) : \|a_i - \mu_i(t_i)\|_{\Theta \times \mathcal{P}_i} < \sqrt{\varepsilon} \right\};
\]

(b) for every integer \( k \geq 0 \), \( i \in I \) and \( s_i, t_i \in T_i \) with \( d_{T_i, \mathcal{P}}(s_i, t_i) > \delta \),

\[
R^k(s_i, G, 2\varepsilon) \cap \left\{ a_i \in A_i \cap \varphi_i^{-1}(\mathcal{P}_i(t_i)) : \|a_i - \mu_i(t_i)\|_{\Theta \times \mathcal{P}_i} < \sqrt{\varepsilon} \right\} = \emptyset.
\]

Proof. To prove (a), we will show that the pair of correspondences \( \xi_i : T_i \Rightarrow A_i, i \in I \), defined by

\[
\xi_i(t_i) = \left\{ a_i \in A_i \cap \varphi_i^{-1}(\mathcal{P}_i(t_i)) : \|a_i - \mu_i(t_i)\|_{\Theta \times \mathcal{P}_i} < \sqrt{\varepsilon} \right\} \quad \forall t_i \in T_i,
\]

which is nonempty-valued by (i) of Lemma 7, has the \( \varepsilon \)-best-reply property. Indeed, given any \( a_i \in \xi_i(t_i) \) and any conjecture \( \sigma_{-i} : \Theta \times T_{-i} \rightarrow \Delta(A_{-i}) \) with \( \supp \sigma_{-i}(\theta, t_{-i}) \subseteq \xi_{-i}(t_{-i}) \) for all \( (\theta, t_{-i}) \in \Theta \times T_{-i} \), we must have

\[
\pi_{t_i, \sigma_{-i}}(\theta \times (A_{-i} \cap \varphi_i^{-1}(E))) = \mu_i(\theta \times E|t_i) \quad \forall \theta \in \Theta, E \in \mathcal{P}_i.
\]
and hence, \[ \| a_i - \pi^P_{\theta, a_i} \| = \| a_i - \mu_i(t_i) \|_{\Theta \times \mathcal{P}_-} < \sqrt{\varepsilon}, \]
by (i) of Lemma 7. It then follows by (iii) of Lemma 7 that \( a_i \in BR_i(\pi_{t_i, a_i}, G, \varepsilon) \). We have thus shown that the profile of correspondences \((\xi_t)_{t \in I}\) has the \( \varepsilon \)-best-reply property.

Turning to (b), since \( d^0_{i, \mathcal{P}} \equiv 0 \) the result is true for \( k = 0 \) (vacuously). Proceeding by induction, assume the result is true for \( k \geq 0 \) and let us show that it remains true for \( k + 1 \). Fix \( i \in I \) and \( s_i, t_i \in T_i \) with \( d^{k+1}_{i, \mathcal{P}}(s_i, t_i) > \delta \). Then, there is some \( \theta \in \Theta \) and some \( E \in \mathcal{P}_- \) such that
\[
\mu_i(\theta \times E^\delta_{\mathcal{P}}|s_i) < \mu_i(\theta \times E|t_i) - \delta/(\# \Theta \cdot \# \mathcal{P}_-). \tag{25}
\]

Consider an arbitrary \( k \)-order \( 2\varepsilon \)-rationalizable conjecture \( \sigma_{-i} : \Theta \times T_{-i} \to \Delta(A_{-i}) \). By the induction hypothesis, for every \( s_{-i}, t_{-i} \in T_{-i} \), every \( \theta \in \Theta \) and every \( a_{-i} \in A_{-i} \) with \( \| a_{-i} - \mu_{-i}(t_{-i}) \|_{\Theta \times \mathcal{P}_{-i}} < \sqrt{\varepsilon} \), we can have \( \sigma_{-i}(\theta, s_{-i})[a_{-i}] > 0 \) only if \( d^k_{-i, \mathcal{P}}(s_{-i}, t_{-i}) \leq \delta \). In particular, for every \( s_{-i}, t_{-i} \in T_{-i} \), every \( \theta \in \Theta \) and every \( a_{-i} \in A_{-i} \),
\[
(\mu_{-i}(t_{-i})|_{\Theta \times \mathcal{P}_{-i}} = a_{-i} \quad \text{and} \quad d^k_{-i, \mathcal{P}}(s_{-i}, t_{-i}) > \delta) \implies \sigma_{-i}(\theta, s_{-i})[a_{-i}] = 0.
\]

It follows that for every \((\theta, s_{-i}) \in \Theta \times T_{-i}, \)
\[
s_{-i} \notin E^\delta_{\mathcal{P}} \implies \sigma_{-i}(\theta, s_{-i})[A_{-i} \cap \varphi_{-i}^{-1}(E)] = 0, \tag{26}
\]

since for every \( a_{-i} \in A_{-i} \cap \varphi_{-i}^{-1}(E) \) and every \( t_{-i} \in T_{-i} \) with \( \mu_{-i}(t_{-i})|_{\Theta \times \mathcal{P}_{-i}} = a_{-i} \) we must have \( t_{-i} \in E \). Hence, for every \( k \)-order \( 2\varepsilon \)-rationalizable conjecture \( \sigma_{-i} \) we have
\[
\pi_{s_i, \sigma_{-i}}(\theta \times (A_{-i} \cap \varphi_{-i}^{-1}(E))) = \int_{T_{-i}} \sigma_{-i}(\theta, s_{-i})[A_{-i} \cap \varphi_{-i}^{-1}(E)] \mu_i(\theta \times d_{s_{-i}}|s_i) \]
\[
= \int_{E^\delta_{\mathcal{P}}} \sigma_{-i}(\theta, s_{-i})[A_{-i} \cap \varphi_{-i}^{-1}(E)] \mu_i(\theta \times d_{s_{-i}}|s_i) \quad \text{(by (26))}
\]
\[
\leq \mu_i(\theta \times E^\delta_{\mathcal{P}}|s_i)
< \mu_i(\theta \times E|t_i) - \delta/(\# \Theta \cdot \# \mathcal{P}_-), \quad \text{(by (25))}
\]

and thus, \( \| \pi^P_{s_i, \sigma_{-i}} - \mu_i(t_i) \|_{\Theta \times \mathcal{P}_{-i}} > \zeta \). It follows from part (iv) of Lemma 7 that
\[
R^{k+1}_i(s_i, G, 2\varepsilon) \cap \left\{ a_i : \| a_i - \mu_i(t_i) \|_{\Theta \times \mathcal{P}_{-i}} < \sqrt{\varepsilon} \right\} = \emptyset,
\]
as was to be shown. 

\[\text{Corollary 2.} \]
For every frame \( \mathcal{P} \) and \( \delta > 0 \) there exists \( \varepsilon > 0 \) and a game \( G \) with \( |G| \leq M \) such that for every \( i \in I \) and \( s_i, t_i \in T_i \),
\[
d^W_{i, \mathcal{P}}(s_i, t_i) > \delta \implies R_i(t_i, G) \not\subset R_i(s_i, G, \varepsilon).
\]

38
Proof. A straightforward implication of Lemma 8 is that for some \( \varepsilon > 0 \) and some game \( G' \) with \( |G'| \leq M \), for every \( i \in I \) and \( s_i, t_i \in \mathcal{T}_i \) we have
\[
d_{i, \mathcal{P}}(s_i, t_i) > \delta \implies R_i(t_i, G', \varepsilon) \not\subseteq R_i(s_i, G', 2\varepsilon).
\]

To conclude, we can use a construction similar to the last part of the proof of Lemma 4 to obtain a game \( G \) with \( R_i(\cdot, G, \gamma) = R_i(\cdot, G', \gamma + \varepsilon) \) for all \( \gamma \geq 0 \). 

\[\blacksquare\]

The only if direction of Theorem 2 is an immediate implication of Corollary 2.

### A.4 Proof of Theorem 3

We need the following piece of notation. Given an integer \( m \geq 1 \), a measurable subset \( E \subseteq \Omega \) and \( p \in [0, 1]^2 \), define the event that \( E \) is \( m \)-order \( p \)-belief recursively as follows:
\[
[B^p]^m(E) \overset{def}{=} B^p \left( E \setminus \left[ B^p \right]^{m-1}(E) \right),
\]
where \( [B^p]^0(E) \overset{def}{=} \Omega \). Then, the event that \( E \) is \( m \)-order \( p \)-belief for player \( i \), written \( [B^p_i]^m(E) \), is the projection of \( [B^p]^m(E) \) onto \( \mathcal{T}_i \). We these definitions in place, we have:
\[
C^p(E) = \bigcap_{m \geq 1} [B^p]^m(E) \quad \text{and} \quad C^p_i(E) = \bigcap_{m \geq 1} [B^p_i]^m(E).
\]

**Lemma 9.** For every integer \( k \geq 1 \) and \( \delta > 0 \) there exists a \( k \)-order frame \( \mathcal{P} \) such that, for every \( i \in I \), every atom of \( \mathcal{P}_i \) has \( d^k_i \)-diameter at most \( \delta \).

**Proof.** For \( k = 1 \) the result is trivial, as any profile of first-order measurable partitions is a frame. Proceeding by induction, consider \( k \geq 1 \), fix \( \delta > 0 \) and let \( \mathcal{P} \) be a \( k \)-order measurable frame whose atoms all have \( d^k_i \)-diameter less than \( \delta/2 \). Let \( \Pi_i \) be a finite partition of the simplex \( \Delta(\Theta \times \mathcal{P}_i) \) (viewed as a subset of the Euclidean space \( \mathbb{R}^{#\Theta \times \#\mathcal{P}_i} \)) into finitely many Borel measurable subsets with Euclidean diameter less than \( \delta/\sqrt{#\Theta \times \#\mathcal{P}_i} \). By Lemma 2, the join \((\mathcal{P}_i \vee (\Pi_i/\mathcal{T}_i))_{i \in I}\) is a \((k+1)\)-order frame. We claim that every atom of \( \mathcal{P}_i \vee (\Pi_i/\mathcal{T}_i) \) has \( d^{k+1}_i \)-diameter less than \( \delta \). Let \( s_i, t_i \) be a pair of types with \( s_i \in (\mathcal{T}_i/\Pi_i)(t_i) \), let \( E \) be a measurable subset of \( \Theta \times \mathcal{T}_i \) and let us show that \( \mu_i(E^{\delta,k}|s_i) \geq \mu_i(E|t_i) - \delta \). Since all the atoms of \( \mathcal{P}_i \) have \( d^{k}_i \)-diameter less than \( \delta/2 \), there is some \( F \in 2^{\Theta} \otimes \mathcal{P}_i \) with \( E \subseteq F \subseteq E^{\delta/k} \). Then, \( |\mu_i(F|s_i) - \mu_i(F|t_i)| < \delta \), because every atom of \( \Pi_i \) has Euclidean diameter less than \( \delta/\sqrt{#\Theta \times \#\mathcal{P}_i} \) and we have \( s_i \in (\mathcal{T}_i/\Pi_i)(t_i) \). Thus,
\[
\begin{align*}
\mu_i(E^{\delta,k}|s_i) &\geq \mu_i(F^{\delta/k}|s_i) & (\text{by } F \subseteq E^{\delta/k}) \\
&\geq \mu_i(F|s_i) & (\text{by } F \subseteq F^{\delta/k}) \\
&\geq \mu_i(F|t_i) - \delta & (\text{by } |\mu_i(F|s_i) - \mu_i(F|t_i)| < \delta) \\
&\geq \mu_i(E|t_i) - \delta & (\text{by } E \subseteq F)
\end{align*}
\]
as claimed. 

\[\blacksquare\]
Lemma 10. Fix $\delta > 0$, an integer $k \geq 1$ and a $k$-order frame $\mathcal{P}$ whose atoms all have $d_i^k$-diameter less than $\delta$ for every $i \in I$. Then, for every $m = 0, \ldots, k$,

$$d_i^m(s_i, t_i) \leq d_i^m(\mathcal{P})(s_i, t_i) + m\delta \quad \forall s_i, t_i \in \mathcal{T}_i, \forall i \in I.$$  

Proof. Fix $\delta > 0$, an integer $k \geq 1$ and a $k$-order frame $\mathcal{P}$ whose atoms all have $d_i^k$-diameter less than $\delta$, for every $i \in I$. (Such a frame exists by Lemma 9.) For $m = 0$ the conclusion of the lemma is trivial, as $d_i^0 = d_i^0(\mathcal{P}) = 0$. Consider $1 \leq m \leq k$ and assume the conclusion of the lemma holds for $m - 1$. Let $s_i, t_i \in \mathcal{T}_i$ and $\eta > d_i^m(\mathcal{P})(s_i, t_i)$ and let us show that $d_i^m(s_i, t_i) \leq \eta + m\delta$.

Fix $E \in 2^\Omega \otimes \mathcal{P}_{-i}$. Since all the atoms of $\mathcal{P}_{-i}$ have $d_{-i}^k$-diameter less than $\delta$, there is some $F \in 2^\Omega \otimes \mathcal{P}_{-i}$ with $E \subseteq F \subseteq E^{\delta,m-1}$. Then,

$$
\mu_i(E^{\eta+m\delta,m-1} | s_i) \geq \mu_i(F^{\eta+(m-1)\delta,m-1} | s_i) \quad (by \ F \subseteq E^{\delta,m-1})
$$

$$
\geq \mu_i(F^{\eta,m-1} | s_i) \quad (by \ d_{-i}^{m-1} \leq d_{-i}^{m-1}(\mathcal{P}) + (m-1)\delta)
$$

$$
\geq \mu_i(F | t_i) - \eta \quad (by \ \eta > d_i^m(\mathcal{P})(s_i, t_i))
$$

$$
\geq \mu_i(E | t_i) - \eta - m\delta, \quad (by \ E \subseteq F)
$$

and hence, $d_i^m(s_i, t_i) \leq \eta + m\delta$. But since our choice of $\eta > d_i^m(\mathcal{P})(s_i, t_i)$ was arbitrary, we have shown that $d_i^m(s_i, t_i) \leq d_i^m(\mathcal{P})(s_i, t_i) + m\delta$, as required. \hfill \blacksquare

Lemma 11. Fix $\delta > 0$, $p \in (0,1]^2$, an integer $k \geq 1$ and an event $E \subseteq \Omega$ that is measurable with respect to a frame $\mathcal{P}$. Let $\mathcal{P}$ denote the common belief frame $(\mathcal{P}_i \cap \{C^p_i(E), \mathcal{T}_i \setminus C^p_i(E)\})_{i \in I}$. Then, for every integer $\ell \geq k$,

$$
(C^p_i(E))^{\delta, \ell}_p \subseteq [B^{p^{\delta,1}}_i]^{\ell-k}_p (E^{\delta,k}_p) \quad \forall i \in I.
$$

Proof. We prove the result by induction on $\ell \geq k$. First, the result is trivial for $\ell = k$, as $[B^{p^{\delta,1}}_i]^{0}_p (\cdot) \equiv \mathcal{T}_i$ for every $i$. Next, suppose the result is true for $\ell \geq k$ and let us show that it remains true for $\ell + 1$. Pick $t_i \in C^p_i(E)$ and $s_i \in \mathcal{T}_i$ with $d_{i,p}^{\ell+1}(s_i, t_i) < \delta$ and let us show that

$$
\begin{align*}
&\quad s_i \in B^{p^{\delta,k}}_i \left( E^{\delta,k}_p \cap [B^{p^{\delta,1}}_i]^{\ell-k}_p (E^{\delta,k}_p) \right) \\
&= [B^{p^{\delta,1}}_i]^{\ell+1-k}_p (E^{\delta,k}_p).
\end{align*}
$$

(27)
Indeed,\footnote{Recall that, for any measurable subset $E \subseteq \Omega$ and any type $t_i$ of player $i$, $E_{t_i}$ denotes the section of $E$ over $t_i$. See Section 2.3.}

$$
\mu_i\left( \left( E^\delta_{\mathcal{F}} \cap \left[ B^p_{\mathcal{F}} \right]^{\ell-k} (E^\delta_{\mathcal{F}}) \right)_{s_i} \middle| s_i \right) \geq \mu_i\left( \left( (E \cap C^p(E))^{\delta,\ell} \right)_{s_i} \middle| s_i \right) \\
\geq \mu_i\left( \left( (E \cap C^p(E))_{t_i} \right)^{\delta,\ell} \middle| s_i \right) \\
\geq \mu_i\left( \left( (E \cap C^p(E))_{t_i} \right) - \delta \right) \\
\geq \mu_i\left( (E \cap C^p(E))_{t_i} - \delta \right) \\
\geq p_i - \delta,
$$

where the first inequality follows from the induction hypothesis and the fact that $d^k_{i,\mathcal{F}} \leq d^\ell_{i,\mathcal{F}}$, the second inequality follows from $d^\ell_{i,\mathcal{F}}(s_i, t_i) < \delta$, the third inequality follows from $d^{\ell+1}_{i,\mathcal{F}}(s_i, t_i) < \delta$ and the last inequality follows from $t_i \in C^p_i(E) = B^p_i((E \cap C^p(E))$. This proves (27).

\section*{Lemma 12}

For every $\delta > 0$, integer $k \geq 1$, $p \in (0, 1]^2$ and measurable $E \subseteq \Omega$ there exists a frame $\mathcal{F}$ such that for every $s_i, t_i \in T_i$ with $d^\ell_{i,\mathcal{F}}(s_i, t_i) < \delta$,

$$
t_i \in C^p_i(E) \implies s_i \in C^{p-\delta(k+2)}_i(E^{\delta(k+2),k}).
$$

\begin{proof}
Fix $\varepsilon > 0$, an integer $k \geq 1$, $p \in (0, 1]^2$ and a measurable set $E \subseteq \Omega$. Let $\tilde{\mathcal{F}}$ be a $k$-order frame whose atoms have $d^k_i$-diameter at most $\delta$, for every player $i$. Fix $i \in I$, pick $F \in 2^\Theta \otimes \mathcal{P}_i$ such that $E \subseteq F \subseteq E^\delta_{\mathcal{F}}$ and consider the common belief frame $\mathcal{F} = \{ \tilde{\mathcal{F}_j} \cup \{ C^p_i(F), T_j \setminus C^p_j(F) \} \}_{j \in I}$. Let $t_i \in C^p_i(E)$ and consider a type $s_i$ with $d^\ell_{i,\mathcal{F}}(s_i, t_i) < \delta$. Since $E \subseteq F$, we have $t_i \in C^p_i(F)$. Then,

$$
s_i \in \bigcap_{\ell \geq k} \left( C^p_i(F) \right)^{\delta,\ell} \subseteq \bigcap_{m \geq 1} \left[ B^p_{\mathcal{F}} \right]^{m} (F^\delta_{\mathcal{F}}) \quad \text{(by $d^\ell_{i,\mathcal{F}}(s_i, t_i) < \delta$ and Lemma 11)}
$$

$$
= C^{p-\delta}_i (F^\delta_{\mathcal{F}}) \quad \text{(by the definition of common belief)}
$$

$$
\subseteq C^{p-\delta}_i (F^{(k+1)\delta,k}) \quad \text{(by Lemma 10)}
$$

$$
\subseteq C^{p-\delta}_i (E^{(k+2)\delta,k}), \quad \text{(by $F \subseteq E^\delta_{\mathcal{F}}$)}
$$

and hence $s_i \in C^{p-(k+2)\delta}_i (E^{(k+2)\delta,k})$.
\end{proof}

\text{Theorem 3} is an immediate implication of Lemma 12 above.
A.5 Proof of Claim 1

First we introduce some notation. For every \( r = (r_1, \ldots, r_4) \in (0, 1]^4, i \in I \), measurable subset \( E \subseteq \Omega \), let \( [M_t^r]^0(E) = \Omega \) and for every positive integer \( k \), define recursively

\[
[M_t^r]^k(E) = B_{i_1}^r(E \cap B_{i_2}^r(E \cap B_{i_3}^r(E \cap [M_t^r]^{k-1}(E)))).
\]

Note that

\[
[M_t^r]^k(E) \subseteq B_{i_1}^r(E \cap [M_t^{r2,r3,r4}]^{k-1}(E)) \subseteq [M_t^r]^{k-1}(E) \quad \forall k \geq 1. \tag{28}
\]

Next, we define the frame \( \mathcal{P} \). For every \( k \geq 1 \), let

\[
P_k^1 = [M_1^{(p,p,p,p)}(\theta_0)], \quad Q_k^1 = [M_1^{(p,p,q,p)}(\theta_0)],
\]
\[
P_k^2 = [M_2^{(p,p,p,q)}(\theta_0)], \quad Q_k^m = [M_2^{(p,q,p,p)}(\theta_0)]
\]

and finally,

\[
P_i = \bigcap_{k=1}^{\infty} P_i^k \quad \text{and} \quad Q_i = \bigcap_{k=1}^{\infty} Q_i^k \quad \forall i \in I.
\]

The frame \( \mathcal{P} \) is the profile of partitions \( (\mathcal{P}_i)_{i \in I} \) where

\[
\mathcal{P}_i \equiv \{P_i \setminus Q_i, Q_i \setminus P_i, P_i \cap Q_i, \mathcal{T}_i \setminus (P_i \cup Q_i)\} \quad \forall i \in I.
\]

To verify that \( \mathcal{P} \) is a frame, note that (28) implies

\[
P_k^1 \subseteq B_{i_1}^r(\theta_0 \times P_{k-1}) \subseteq P_{k-1}^1 \quad \forall k \geq 1
\]

and hence

\[
P_1 = \bigcap_{k=2}^{\infty} P_1^k \subseteq \bigcap_{k=2}^{\infty} B_1^r(\theta_0 \times P_{k-1}) = B_1^r(\theta_0 \times P_2) \subseteq \bigcap_{k=2}^{\infty} P_{k-1}^1 = P_1.
\]

Therefore, \( P_1 = B_1^r(\theta_0 \times P_2) \). By analogous arguments,

\[
Q_1 = B_1^p(\theta_0 \times Q_2), \quad P_2 = B_2^p(\theta_0 \times Q_1), \quad \text{and} \quad Q_2 = B_2^p(\theta_0 \times P_1).
\]

Thus, for all \( i \in I \) and \( t_i \in \mathcal{T}_i \), the element of \( \mathcal{P}_i \) containing \( t_i \) is determined by the values \( \mu_i(\theta_0 \times P_{-i}|t_i) \) and \( \mu_i(\theta_0 \times Q_{-i}|t_i) \), and hence, a fortiori, by the restriction of \( \mu_i(\cdot|t_i) \) to \( \Theta \times \mathcal{P}_{-i} \).

We now prove that \( t_1^n \not\rightarrow t_1 \) uniform-weakly on \( \mathcal{P} \). Fix \( 0 < \delta < \min\{p, \Delta\} \). It is enough to show that for every positive integer \( n \),

\[
d_{1,3}^{4n-3}(t_1^n, t_1) > \delta, \quad d_{2,3}^{4n-2}(s_2^n, s_2) > \delta, \quad d_{1,3}^{4n-1}(s_1^n, s_1) > \delta, \quad d_{2,3}^{4n}(t_2^n, t_2) > \delta. \tag{29}
\]

To prove this, we will show that for \( n = 1 \), the first inequality holds, and that for any \( n \geq 1 \), if the first inequality holds for \( n \), then all others also hold for \( n \), and if the last inequality holds for
n, then the first holds for \( n + 1 \). In the proof we will use the following facts, which are immediate from the definition of \( t_1, t_2, s_1, s_2 \) and the fact that \( \mu_i(\theta_0 | r_i) = 0 \) and \( P_i \cup Q_i \subseteq B_i^{\delta}(\theta_0) \) for each \( i \in I \):

\[
t_1 \in P_1, \quad s_1 \in Q_1, \quad s_2 \in Q_2, \quad t_2 \in P_2, \quad r_i \notin (P_i \cup Q_i)^{\delta,1} \quad \forall i \in I. \tag{30}
\]

Since \( \mu_1(\theta_0 | t_1) = 1 \) and \( \mu_1(\theta_0 | r_1^1) = 0 \), we have \( d_{1,\delta}(t_1^1, t_1) = 1 > \delta \), which proves the first inequality in (29) for \( n = 1 \). Now fix any \( n \geq 1 \) and assume the first inequality in (29) holds for \( n \). Then, by (30), \( \{t_i^n, r_1\} \cap (P_1)^{\delta,4n-3} = \emptyset \). Since \( \mu_2(\theta_0 \times \{t_i^n, r_1\} | s_i^n) = 1 \) and, by (30), \( \mu_2(\theta_0 \times P_1 | s_2) = \mu_2(\theta_0, t_1 | s_2) = p \), it follows that \( d_{2,\delta}^{4n-2}(s_2^n, s_2) \geq p > \delta \). Thus, the second inequality in (29) holds for \( n \). The latter implies, by (30), \( \{s_2^n, r_2\} \cap (P_2)^{\delta,4n-2} = \emptyset \), and since \( \mu_1(\theta_0 \times \{s_2^n, r_2\} | s_1^n) = 1 \) and, by (30), \( \mu_1(\theta_0 \times Q_2 | s_1) = \mu_1(\theta_0, s_2 | s_1) = p \), we also have \( d_{1,\delta}^{4n-1}(s_1^n, s_1) \geq p > \delta \), i.e., the third inequality in (29) holds for \( n \). This in turn implies, by (30), \( \{s_i^n, r_1\} \cap (P_1)^{\delta,4n-1} = \emptyset \), and since \( \mu_2(\theta_0 \times \{s_i^n, r_1\} | t_i^n) = 1 \) and, by (30), \( \mu_2(\theta_0 \times Q_1 | t_2) = \mu_1(\theta_0, s_1 | t_2) = p \), we obtain \( d_{2,\delta}^{4n}(t_2^n, s_2) \geq p > \delta \). This proves that the fourth inequality in (29) holds for \( n \), and hence, by (30), that \( \{t_i^n, r_2\} \cap (P_2)^{\delta,4n} = \emptyset \). It remains to show that the latter implies that the first inequality in (29) holds for \( n + 1 \). Indeed, since \( \mu_1(\theta_0 \times \{t_i^n, r_2\} | t_i^{n+1}) = 1 - q + \Delta \) and, by (30), \( \mu_1(\theta_0 \times P_2 | t_1) = \mu_1(\theta_0, t_2 | t_1) = q \), we have \( d_{1,\delta}^{4n+1}(t_1^{n+1}, t_1) \geq \Delta > \delta \), as claimed.

### A.6 Proof of Theorem 4

It is enough to prove the implication (e) \( \Rightarrow \) (a), since the implications (a) \( \Leftrightarrow \) (b) \( \Rightarrow \) (c) \( \Leftrightarrow \) (d) \( \Rightarrow \) (e) follow from Theorems 1, 2 and 3. Fix a finite type space \((T_1, T_2)\). We will show that there exist \( \eta > 0 \) and \( k \geq 1 \) such that for all \( \delta \in (0, \eta), n \geq 0, i \in I \) and \((i, s_i) \in T_1 \times T_2 \) with \( d_i^k(s_i, t_i) < \delta \), one has

\[
s_i \in \left[ B_i^{1(1-\delta)} \right]^n (\Theta \times T_1^\delta \times T_2^\delta) \quad \Rightarrow \quad d_i^{k+n}(s_i, t_i) < 2\delta. \tag{31}
\]

Choose \( k \geq 1 \) and \( \eta > 0 \) so that, for all \( i \in I \) and \( s_i, t_i \in T_i \), if \( d_i^{k-1}(s_i, t_i) < 2\eta \) then \( s_i = t_i \). Since \( T_1 \) and \( T_2 \) are finite, such \( k \) and \( \eta \) exist. Fix \( \delta \in (0, \eta) \). Thus, for all \( n \geq 0, i \in I, t_i \in T_i \) and \( E \subseteq \Theta \times T_{-i} \),

\[
E^{\delta,k-1} \cap (\Theta \times T_{-i})^{\delta,k} \subseteq E^{\delta,k}. \tag{32}
\]

The proof of (31) is by induction in \( n \). Obviously, (31) holds for \( n = 0 \). Now assume that (31) holds for some \( n \geq 0 \), and fix \( i \in I, t_i \in T_i \) and \( s_i \in T_i \) with \( d_i^k(s_i, t_i) < \delta \) and \( s_i \in \left[ B_i^{1(1-\delta)} \right]^{n+1} (\Theta \times T_1^\delta \times T_2^\delta) \). Since \( \mu_i(\Theta \times T_{-i} | t_i) = 1 \), in order to prove that \( d_i^{k+n+1}(s_i, t_i) < 2\delta \) it suffices to show that \( \mu_i(E^{2\delta,k+n} | s_i) \geq \mu_i(E | t_i) - 2\delta \) for every \( E \subseteq \ldots
\]
some product-closed proper subset $E$.

Indeed,

$$
\mu_i \left( E^{2\delta,k+n} \right) \geq \mu_i \left( E^{\delta,k} \cap \left[ B^{(1-\delta)1}_{1-i} \right] \times T_{\bar{\delta},k} \right) \mid s_i \rangle
\geq \mu_i \left( E^{\delta,k-1} \cap (\Theta \times T_{\bar{\delta},k}^{(1-\delta)1}) \times T_{\bar{\delta},k} \right) \mid s_i \rangle
\geq \mu_i \left( E^{\delta,k-1} \mid s_i \rangle - \bar{\delta} \geq \mu_i \left( E \mid t_i \rangle - 2\delta. \right.
\right.$$

where the first inequality follows from the induction hypothesis, the second from (32), the third from $s_i \in \left[ B^{(1-\delta)1}_{1-i} \right]_{n+1} \times (T_{\bar{\delta},k})$ and the fourth from $d_{l_i}^{k}(s_i, t_i) < \delta$.

### A.7 Proof of Theorem 5

An immediate implication of Ely and Pęski (2011, Theorem 1) is that every finite type is critical. This fact, together with the denseness of finite types in the strategic topology (proved in Dekel, Fudenberg, and Morris (2006)), implies that the set of critical types is dense in the strategic topology.

Next, we show that the set of critical types is open in the strategic topology, or equivalently, that the set of regular types is closed. Suppose not. Then, there is a sequence of regular types $t_i^n$ that converges to some critical type $t_i$. By Ely and Pęski (2011, Theorem 1), there is some $p > 0$ and some product-closed, proper subset $E \subset \Omega$ with $t_i \in C_{p1}^{(p-\delta)1}(E)$. Then, there is an integer $k \geq 1$ and $\delta \in (0, p)$ such that the $d_{l_i}^{k}$-closure of $E^{\delta,k}$ is a proper subset of $\Omega$. Moreover, by Theorem 3, $t_i^n \to t_i$ in common beliefs, and hence $t_i^n \in C_{p1}^{(p-\delta)1}(E^{\delta,k})$ for all $n$ large enough. It follows, again by Ely and Pęski (2011, Theorem 1), that $t_i^n$ is a critical type for all $n$ large enough, and this is a contradiction. The contradiction shows that the set of regular types is closed.

Finally, to prove that the set of critical types is finitely prevalent, given a pair of types $u_i$, $u'_i$ and $\alpha \in (0, 1)$, define

$$
u''_i = \alpha u_i + (1 - \alpha)u'_i = \mu_i^{-1}(\alpha \mu_i(u_i) + (1 - \alpha)\mu_i(u'_i)).$$

We show that $u''_i$ is regular if and only if $u_i$ and $u'_i$ are both regular. To prove the “only if” part, suppose that $u_i$ is critical. By Ely and Pęski (2011, Theorem 1), $u_i \in C_{p1}^{(p-\delta)1}(E_i) = E_i \cap B_{p1}(C_{p1}^{(p-\delta)1}(E_i))$ for some product-closed proper subset $E_i \subset \bar{T}_i$, and this clearly implies $u''_i \in \left( E_i \cup u'_i \right) \times B_{p1}(C_{p1}^{(p-\delta)1}(E_i \cup u''_i)) = C_{p1}^{(p-\delta)1}(E_i \cup u''_i)$, which implies $u''_i$ is critical. Conversely, if $u''_i$ is critical, then, by Theorem 1 in Ely and Pęski (2011), $u''_i \in C_{p1}^{(p-\delta)1}(E_i)$, $E_i \cap B_{p1}(C_{p1}^{(p-\delta)1})$ for some product-closed proper subset $E_i \subset \bar{T}_i$ and some $p > 0$. Since $u''_i = \alpha u_i + (1 - \alpha)u'_i$, either $u_i \in B_{p1}(C_{p1}^{(p-\delta)1}(E_i))$ or $u'_i \in B_{p1}(C_{p1}^{(p-\delta)1}(E_i))$, thus either $u_i$ or $u'_i$ is critical. The conclusion that the set of critical types is finitely prevalent now follows from Heifetz and Neeman (2006, Lemma 1).
A.8 Proof of Theorem 6

The proof of the theorem uses the following lemma, a generalization of Theorem A in Monderer and Samet (1989), which in turn generalizes Aumann’s (1976) agreement theorem. It says that if a common prior type commonly $(p, p)$-believes, for some $p > 0$, that each player $i$’s belief in a fixed event $D$ lies in an interval of a given size $\delta$ around some fixed value $r_i$, then the difference between the values $r_1$ and $r_2$ is bounded above by a number that vanishes for sufficiently large $p$ and small $\delta$.

**Lemma 13.** Let $r_1, r_2 \in [0, 1]$, $p \in (0, 1]$ and $\delta \in [0, 1]$. Let $D \subseteq \Theta \times \mathcal{T}_1 \times \mathcal{T}_2$ be a measurable set and define $E_i = \{ t_i \in \mathcal{T}_i : |\mu_i(D_{t_i} | t_i) - r_i | \leq \delta \}$, $i \in I$. If, for some $i$, $C_i^{p,1}(\Theta \times E_1 \times E_2)$ contains a common prior type of player $i$, then $|r_1 - r_2| \leq 1 - p + 2\delta$.

**Proof.** Let $F = C_i^{p,1}(\Theta \times E_1 \times E_2)$ and $F_i = C_i^{p,1}(\Theta \times E_1 \times E_2)$ for each player $i$. Suppose $F_i \cap T_i \neq \emptyset$ for some $i$, where $(T_i)_{i \in I}$ is a countable common prior type space with prior $\eta$. Then, since $p > 0$, we must have $F_i \cap T_i \neq \emptyset$ for every player $i$. Moreover, we have $F_i \subseteq E_i$. Thus, since $\eta(\cdot | t_i) = \mu_i(\cdot | t_i)$ for every $t_i \in T_i$, it follows that $|\eta(D | F_i) - r_i | \leq \delta$. Similarly, since $F_i \subseteq B_i^p(F)$, we have $\eta(F | F_i) \geq p$. Thus, since $F \subseteq F_i$, for any event $D' \subseteq \Omega$ we get

$$\eta(D' | F_i) \geq \eta(D' \cap F | F_i) = \eta(F | F_i) \eta(D' | F) \geq p \eta(D' | F).$$

Plugging first $D$ and then its complement for $D'$ in the latter expression, we obtain

$$r_i + \delta \geq \eta(D | F_i) \geq p \eta(D | F), \quad r_i - \delta \leq \eta(D | F_i) \leq 1 - p + p \eta(D | F).$$

and hence $p \eta(D | F) - \delta \leq r_i \leq p \eta(D | F) + 1 - p + \delta$. Since the latter inequalities hold for every player $i$, the result follows.

As a preliminary step, we prove the existence of a finite type $t_i$ that cannot be approximated uniform weakly by any sequence of common prior types. Let $\theta_1$ and $\theta_2$ be distinct elements of $\Theta$. Consider the type space $(T_i)_{i \in I}$ where, for each $i \in I$, $T_i$ is a singleton, $T_i = \{ t_{i1} \}$, and beliefs are such that $\mu_i(\cdot | t_{i1}) = 1$. Fix $\delta \in (0, 1/3)$. Letting $D = \{ \theta_1 \} \times \mathcal{T}_1 \times \mathcal{T}_2$, $p = 1 - \delta$, $r_1 = 1$ and $r_2 = 0$ in Lemma 13, we see that for each player $i$, $C_i^{p,1}(B_{1}^p(\theta_1) \cap B_{2}^p(\theta_2))$ contains no common prior types of $i$. Since $t_i \in C(1)(B_{1}^1(\theta_1) \cap B_{2}^1(\theta_2))$, we conclude that there is no sequence of common prior types converging to $t_i$ in common beliefs, and hence, by Theorem 3, no sequence of common prior types converging to $t_i$ uniform weakly. Thus, we can find $\varepsilon \in (0, 1)$ such that $d_i^{uw}(t_i, s_i) > \varepsilon$ for every $i$ and every common prior type $s_i$.

Now, to show that the set of common prior types is nowhere dense in the universal type space under the strategic topology, fix any $t_i \in \mathcal{T}_i$. We prove the existence of a sequence of finite

---

37 Neeman (1996) proves the claim for $\delta = 0$, improving on the bound originally given by Monderer and Samet (1989). Aumann (1976) proves the result for $\delta = 0$ and $p = 1$. 

45
types, \( t_i^n \), that converges to \( u_i \) strategically and satisfies \( d_i^{uw}(t_i^n, s_i) > \epsilon/n \) for every \( n \) and every common prior type \( s_i \). Since each \( t_i^n \) is finite, this implies, by Theorem 4, that no \( t_i^n \) is in the strategic closure of the set of common prior types, and hence that the complement of that closure is dense, thus proving the nowhere denseness of common prior types. To define the sequence of finite types \( t_i^n \), pick an arbitrary sequence of finite types, \( u_i^n \), converging to \( u_i \) strategically—such sequence exists by Theorem 3 in Heifetz, Fudenberg, and Morris (2006)—, and for each \( n \) define \( t_i^n \) by

\[
\mu_i(\cdot|t_i^n) = \frac{n-1}{n} \mu_i(\cdot|u_i^n) + \frac{1}{n} \mu_i(\cdot|t_i). 
\]

Since \( u_i^n \) and \( t_i \) are finite, so is \( t_i^n \). Moreover, \( d_i^{uw}(t_i^n, u_i^n) \leq 1/n \) for every \( n \). Since the sequence \( u_i^n \) converges strategically to \( u_i \), we conclude by Theorem 1 that the sequence \( t_i^n \) also converges strategically to \( u_i \). It remains to prove that \( d_i^{uw}(t_i^n, s_i) > \epsilon/n \) for every \( n \) and every common prior type \( s_i \). Indeed, assume, on the contrary, that \( d_i^{uw}(t_i^n, s_i) \leq \epsilon/n \) for some \( n \) and common prior \( s_i \). Then, since \( \mu_i(t_i^n|t_i^n) \geq 1/n \), we have \( \mu_i(t_i^n|\Gamma_{|k}^n|s_i) \geq (1-\epsilon)/n \) for every \( k \geq 1 \). Thus, we also have \( \mu_i(\{|s_{-i} \in T_{-i} : d_i^{uw}(s_{-i}, t_{-i}) \leq \epsilon/n|s_i\}) = \mu_i(\bigcap_k \{t_i^n|\Gamma_{|k}|s_i\}) \geq (1-\epsilon)/n > 0 \). Since \( s_i \) is a common prior type of player \( i \), \( \mu_i(\cdot|s_i) \) is supported in the set of common prior types of player \( -i \). Thus, \( d_i^{uw}(t_{-i}, s_{-i}) \leq \epsilon/n \leq \epsilon \) for some common prior type \( s_{-i} \). This is a contradiction, as we have shown in the preliminary step that there is no common prior type that is \( \epsilon \)-close to \( t_{-i} \) in the uniform weak distance.

We now show that the set of common prior types is finitely shy, thus concluding the proof of the theorem. For each player \( i \), consider the set of types defined by

\[
T_i^0 = \{ u_i \in T_i \mid \mu_i(\Theta \times \{t_{-i}\}|u_i) = 0 \},
\]

where \( \{ \{t_i\}_i \} \in I \) is the singleton type space defined in the preliminary step above. Next, for all \( u_i, u_i' \in T_i \) and \( \alpha \in (0,1) \), define

\[
u''_i = \alpha u_i + (1-\alpha)u_i' = \mu_i^{-1}(\alpha \mu_i(\cdot|u_i) + (1-\alpha)\mu_i(\cdot|u_i')).
\]

The set \( T_i^0 \) is a proper face of \( T_i \), i.e. \( \alpha u_i + (1-\alpha)u'_i \in T_i^0 \) if and only if \( u_i, u_i' \in T_i^0 \). Thus, by Heifetz and Neeman (2006, Lemma 1), the set \( T_i^0 \) is finitely shy.

We now prove that the set of common prior types is contained in \( T_i^0 \) by showing that for every type \( u_i \) the inequality \( \mu_i(\Theta \times \{t_{-i}\}|u_i) > 0 \) implies that \( u_i \) is not a common prior type. Suppose that \( u_i \) is a common prior type contained in a countable common prior type space \( (T_i')_{i \in I} \) with prior \( \eta \). Since \( \eta_i(u_i) > 0 \) and \( \mu_i(\Theta \times \{t_{-i}\}|u_i) > 0 \), it follows that \( t_i \in T_i' \) and \( t_{-i} \in T_{-i}' \). Thus, \( \eta_i(t_i) > 0 \) and \( \eta_{-i}(t_{-i}) > 0 \). Moreover, since, \( \mu_i(t_i, t_{-i}|t_i) = 1 \) and \( \mu_{-i}(t_{-i}, t_i|t_{-i}) = 1 \), it follows that

\[
\frac{\eta(t_i, t_{-i})}{\eta_i(t_i)} = 1 \quad \text{and} \quad \frac{\eta(t_{-i}, t_i)}{\eta_{-i}(t_{-i})} = 1.
\]

The first equality above implies that \( \eta((\Theta \times \{t_i\} \times T_{-i}')) \setminus ((\Theta \times \{t_i\} \times T_{-i})) = 0 \). In particular,

\[
\eta(\{t_{-i}, t_i, t_{-i}\}) = 0.
\]
The second equality in (33) implies that
\[ \eta \left( \left( \Theta \times T_i^i \times \{t_{-i}^j \} \right) \setminus \{(\theta_{-i}, t_i, t_{-i})\} \right) = 0. \] (35)

It follows from (34) and (35) that \( \eta \left( \Theta \times T_i \times \{t_{-i}^j \} \right) = 0 \). This contradicts our earlier conclusion that \( \eta_{-i}(t_{-i}) > 0 \). Thus, \( u_i \) is not a common prior type.

Being contained in the finitely shy set \( T_i^0 \), the set of common prior types is also finitely shy.
